THE BUILDERS' JOURNAL

AND ARCHITECTURAL RECORD

APPEALING TO THOSE ENGAGED IN

THE ART OF BUILDING.

IT is our aim, our ambition, our aspiration even, to build our Journal worthily and well, not for the hour only, but for future years; for the few men in the forefront of an enduring and a laborious Art; for the disciplined ranks of a distinguished Profession; for the young men—Architects to be—and for all who love a clustered column or a flying buttress, a traceried window or a Greek frieze; for the man, too, who honestly plumbs a jamb.

EFFINGHAM HOUSE,
ARUNDEL STREET,
STRAND, W.C.

An Architectural Causerie.

A Student's Library. FEW things are of more importance to an architectural student than that he should possess a collection of well-selected books. In most cases it is essential that they should not be costly—valuable works of reference can be consulted at public libraries if required, and can be purchased only by the well-to-do—but in any event they ought to be full, complete, accurate, and modern; while to buy a cheap book solely because it is cheap is the worst of all possible economies. In the realm of architectural history, for example, there is a wide range of choice, and yet for the youthful student there is only one book, Hamlin's "History of Architecture." Many others are nearly or quite as good, but none are more accurate at so moderate a price. It must, of course, be supplemented if any particular period is to be studied, as with Anderson's "Italian Renaissance," to give a specimen only of possible specialisation without any excessive expense being incurred. A study of details almost necessarily goes contemporaneously with that of history, and while Glazier's "Historic Ornament" may assist, specialisation is essential, and the necessary works are costly, comprising almost of necessity Watts' work on Grecian ornament, Prentice's "Spanish Renaissance," and Colling's "Gothic Ornament"; while works upon Italian and English Renaissance are said to be likely to appear shortly, some which have long been well known being now out of print. The simple rules of building construction are clearly set forth in Mitchell's two volumes, which may well be supplemented by study of his "Forty Plates;" but "Notes on Building Construction," Vol. III. (long known as "Rivington"), still remains the leading work on materials, though, as it was published many years ago, it must be read with caution and with careful comparison with "Specification," the best general and practical book of reference extant. In the direction of tools and plant a good deal of supplementary information is to be obtained from Seddon's "Builder's Work." As a general rule all quantity surveyors should possess Leaning's book on the subject of quantities, but for some purposes and in some districts either "Dobson and Tarn" or "Fletcher" are to be preferred. The beginner should possess Davis's "Quantities and Quantity Taking," which has just been published. Stevenson's "Estimating" is the one book of real value upon pricing, as it explains to a student how to analyze and arrive at prices for himself; "Specification," again, being the work of reference. Coleman's "Sanitary House Drainage" may well form the elementary book upon sanitary matters, but the subject is important enough to carry further, for which purpose either Moore's "Sanitary Engineering" or else "Modern House Construction" may be used. Theoretical cal-

culation is often left to engineers, and unfortunately so, for the subject is a fascinating one when once the initial difficulties have been overcome, so that Middleton's "Stresses and Thrusts" may well be added to this small library of elementary works, Ewing's "Strength of Materials" being the best, as it is also the most modern work, for the advanced student. G. A. T. M.

London University. THE announcement that the University of London is to move its quarters to the Imperial Institute has called public attention to the building which they are about to leave. It is rather a far cry from Burlington Gardens to South Kensington, and it may be questioned if the University may not regret their old home so centrally and conveniently situate. It is not generally known

West End of the use of statuary as an integral part of architectural design. The street is a narrow one, but although the façade could be better seen in a wider thoroughfare, it is still most effective, and the suddenness with which it confronts the spectator in a confined space reminds one of some of the older buildings of Italy. The design consists of a central block with lower wings on either side; from the centre a portico, one storey high, advances and arrests the eye with seated statues at its outer edge; these are flanked at each end of the portico by terminal piers. Behind the portico rises the main block, with columns between the tall windows; against the sky, crowning the composition, are six very fine statues of Galen, Cicero, Aristotle, Plato, Archimedes and Justinian; they are flanked by two small square towers bearing a clock and a wind-dial, both unfortunately very dirty. The wings are of lower elevation; the basement is without windows, the courses lightly

FIG. 1.—FRONT DOOR, 26, DUKE STREET, LIVERPOOL. DRAWN BY M. HONAN. (See p. 3.)

that South Kensington at one time was very nearly being made into a Government quarter, virtually shifting the centre of London life permanently to the west. The Prince Consort favoured a scheme for a vast series of buildings on the ground belonging to the Commissioners of the Great Exhibition of 1851; as they were severally completed they were to be occupied by the Government departments, Whitehall and its neighbourhood being deserted. This was before the scheme for embanking the Thames was put forward; that great work fortunately preserved Whitehall as the historic seat of government, and South Kensington became a land of museums. The University Buildings in Burlington Gardens merit attention for several reasons, and primarily because they are the best example in the

channelled, broken by niches containing statues; the upper storey has windows grouped in threes with columns between; a cornice marks the floor. Over the whole front runs a light balustrade broken by pedestals of statues. Some brownish-red stone has been used for details in the wings with doubtful effect; fortunately the structure was designed before the days when a basement of polished granite, with red brick, terra-cotta, tiles, and "who can say how many more" materials, was considered indispensable. There is an air of refinement about the building which well befits a university; the effect of the whole is very dignified. The statuary—twenty-two stone figures, six in niches, four seated, and twelve breaking the sky-line—is well distributed, and it is impossible not to regret the absence of this most effective feature from most of our new designs. J. C. P.

THE "BUILDERS' JOURNAL" SHILLING FUND.

TO ERECT HOMES FOR DISCHARGED SOLDIERS.

MOST of our readers are by this time aware of the fact that we have started a Shilling Fund to assist the admirable project that has been set on foot for building a Home of Rest for disabled soldiers as a gift to the nation from the building trades. Full particulars of the scheme have already been given, but for the benefit of any who may not have seen them, we repeat a few details.

Character of the Gift.

The purpose of the gift is to meet as far as possible the needs, which all the patriotic funds hitherto established have to a great extent overlooked, of the permanently disabled soldier discharged from the army with a pension inadequate to supply even the barest necessities of life. It is proposed to erect and equip six cottage homes containing in all 100 beds, and in selecting inmates for the homes preference will be given to soldiers who have at some time been members of one or other of the building trades.

The homes will be erected on a freehold site at Bisley, generously given by Lord Pirbright. Their management and maintenance will be superintended by a special sub-committee of the Sailors' and Soldiers' Help Society, an excellent institution of which H.M. the Queen is patron.

Methods of Helping.

The Executive of the Building Trades Gift, whose address is 1, Waterloo Place, Pall Mall, S.W., invite offers of gifts in kind; they have issued printed details, giving the exact quantities of materials, fittings, &c., required, and those of our readers who wish to help in this way should write for these particulars.

Obviously, however, there are many thousands connected with the building trades whose gifts could not possibly take that form, and in the hope of enlisting the help of many who would otherwise be left out, we have started a Shilling Fund.

By this means all who are in any way connected with the building trades—architects, architects' assistants, draughtsmen, students, builders, clerks of works, foremen, workmen, and apprentices—will be afforded an opportunity of taking their share in the national gift.

The following additional contributions to our Shilling Fund have been received up to Monday afternoon:—

We have a number of collecting forms left which we should be pleased to send to any reader who will make good use of them.

The Workmen's Contribution.

We are pleased to learn from the Executive of the general fund that contributions both in money and in kind are coming in well. An attempt is being made to enlist the help of workmen, whose gifts are being asked for the special purpose of defraying the cost of the labour involved in erecting the homes; many masters have agreed to allow collecting sheets to be posted on their building jobs.

Gifts in Kind.

The following is a complete list of contributions in kind for which promises had been received up to the end of last week at the Offices of the Executive of the gift:—

FOR THE WHOLE OF THE BUILDINGS:

Messrs. Acton and Borman.—The whole of the Glass Paper.

Messrs. D. Anderson and Son, and J. C. Brealbert and Co. (jointly).—The whole of the Slag Wool.

Messrs. Robert Boyle and Son.—The entire natural Ventilation Appliances for the whole of the buildings.

Messrs. Carter and Aynsley.—The entire Locks.

Messrs. S. and E. Collier (Reading).—The entire Ridge Tiles.

Messrs. Diespeker and Co.—The entire Mosaic Flooring for Lobbies, Halls, Lavatories, &c.

Messrs. T. and W. Farmiloe.—The entire Whitelead, Colour, Oil, Turps, Varnish, Brushes, and Paint Pots.

Messrs. Hobbs, Hart and Co.—The entire Locks.

Messrs. G. B. Kent and Sons.—Paint, Toilet, and various Brushes.

Messrs. Nicholls and Clarke.—The whole of the Glazing.

Messrs. T. Rider and Sons.—The Dressers for the whole of the Homes.

Messrs. John Roberts and Son (Leeds).—The whole of the Nails for the Roof.

Messrs. Roberts, Adlard and Co.—The laying of the entire Slating (exclusive of slates).

The Velongo Slate and Marble Quarries.—The entire Damp Course Slates, Slate Shelves Slabs, &c.

Messrs. Webb's Engineering Co. (Birmingham).—The entire Door Fittings and Window Furniture, and the General Ironmongery and Taps.

Messrs. G. A. Williams and Son.—The whole of the Interior Blinds.

Messrs. Doulton and Co.—2,000ft. of Drain Pipes, and Yard Gullies for the Six Homes.

Mr. James Brown.—Moulded Bricks and Ornamental Panels of the whole of the buildings.

Messrs. G. Tucker and Son (Loughborough).—Chimney Pots for all six Homes.

FOR SPECIAL SECTIONS OF THE WORK.

The Asbestos and Asbestic Co.—Asbestic Plaster.

Messrs. G. Aston and Sons.—50cwt. of Ironwork and some Large Girders.

The B. and S. Folding Gate Co.—Indiarubber Flooring for two Bathrooms.

Messrs. Benham and Sons.—Two large Kitchen Ranges.

The Birmingham Blind Co.—A set of Outside Blinds for one Home.

Messrs. John Burton and Co.—10,000ft. run of 4in. by 2in. Rafter and Ceiling Joists.

Mr. Jas. Carmichael.—Six Front Doors and Frames.

Messrs. Colls and Sons.—The complete set of forty Doors for one Home.

The Columbian Fire Proofing Co.—The Construction of the First Floor of One Home.

The Conduit Insulation Co.—Electric Conduits.

Mr. J. F. Ebner.—Pitch Pine Flooring for the Ground Floor of Three Homes.

Messrs. J. C. Edwards (Rusdon).—9,000 Red Pressed 6in. by 6in. Flooring Quarries.

The Expanded Metal Co.—Metal Lathing for exterior walls, floors, and partitions of the Recreation House.

Mr. E. Marshall Fox (for the British and London Non-Flammable Wood Company).—Non-Flammable Wood Joinery and Interior Timber Work for the Recreation House.

Messrs. Alfred Goslett and Co.—Three large Kitchen Ranges with high pressure boilers.

Messrs. Thos. Gregory and Co.—Wood-block Flooring for the Recreation Hall.

Messrs. Hilton, Anderson, Brooks and Co.—50 tons of Portland Cement.

Messrs. H. H. Bros. (Leicester).—The Architraves for one Home.

Messrs. Humphreys.—A 30ft. Iron Building for Work shops.

Messrs. Kirk and Randall.—75 squares of lin. Roof Boarding.

Messrs. Lander and Co.—The Warm Air Grates for the Recreation House.

Messrs. Thos. Lawrence and Sons (Bracknell, Berks.).—25,000 Red facing bricks, and 500ft. of molded bricks.

Messrs. Wm. Lee, Son and Co.—25 tons of Portland Cement and 50 yards of Lime.

Messrs. Lindsay, Neal and Co.—The Heavy Girders for a Pair of Homes.

Mr. E. Lucas.—A Service Lift.

Messrs. Macevoy and Holt (North Fleet).—50 tons Cement.

Messrs. McNeil and Co.—The Slag Wool and Roof Felting for one Home.

The Mural Decoration Syndicate.—503yds. of Partitions.

Messrs. John Newton and Co.—The Roof Felting and the "Plasterers' Hair" for three Homes.

Lord Penrhyn (Penrhyn Quarries).—10,000 Slates.

Mr. Assheton Smith (Dinorwic Quarries).—10,000 Slates.

Messrs. Strode and Co.—The Electric Fittings for one Home.

The Town Company, Ltd. (Birmingham).—Twenty-five Enamel Slate Mantlepieces.

Messrs. Geo. Trollope and Sons.—Doors, Casements, and Linings for one Home.

Messrs. Twyford.—The Sanitary Fittings for one Home.

Messrs. B. Ward and Co.—An Artificial Stone Staircase for one Home.

Mr. John P. White (Leicester).—Mantlepieces, designed by the late G. H. Morris, and Garden Seats.

Messrs. Geo. Wooliscroft and Son (Hanley).—The Roofing Tiles for one Home.

Messrs. Maw and Co. (Shropshire).—250 yards super. Tiling for paving.

Mr. George Jennings (preliminary).—Sanitary Fittings for one Home.

Moorgate Engineering Co.—Iron Staircase for Recreation House.

Mr. Jabez Thompson (Northwich, Cheshire).—1,000 Patent Brickwoods.

Mr. William Wiffen (Holsworthy, Devon).—Oak Lintels for one Home.

Darbishers' Granite Quarries (Penmaenmawr).—Some Granite for Macadam.

Messrs. Towers and Williamson (Grantham).—Clinkers for Workshops and Stable floors.

The British Uralite Co.—18,000 square feet of Uralite Slabs.

In addition to the above the following contributions in money have been received:—

Messrs. Sprague and Co.—Lithography.

Messrs. Rich and Co.—Electrography.

DOORS AND DOORWAYS.*

By M. HONAN.

MOST, if not all, of the old work that now remains in Liverpool was done during the seventeenth and eighteenth centuries and belongs to the Queen Anne and Georgian periods, the latter sometimes being called the "portico period." As regards the front doors of many of the old houses of these dates, we find the six-panelled door a great favourite, and it may, in fact, be hailed as a typical Liverpool door. In design, it was formed the same as most doors, the only difference being that the two panels below the lock rail were flush with the stiles, &c. The only line showing the shape of the panel was a small bead worked on the stiles and rails. (I might here add that I am not aware of a door of this kind in any other town, which is the reason why I call it a typical Liverpool door.)

The general effect of this door is very satisfactory, and it has the air of solidity and security, which no doubt was essential in those days when riots and other street troubles were of common occurrence. As for examples of this door, there is one at No. 26, Duke Street (see Fig. 1). The fanlight has long since disappeared and is now replaced by a sheet of modern plate glass. Park Lane, Pitt Street and Kent Square have many examples of this kind of door.

Another very common form of external door is that with eight panels, four raised panels above and four below the lock rail, the upper ones in each case being the smaller. This form is very simple and (to my mind) very effective, and is also very strong and practical, as it has five rails and four muntins, which afford ample accommodation for furniture, such as knocker, letter-box, lock and handle. This kind of door dispenses with the wide lock rail which is generally considered to be very troublesome to get to look right. I might here add that it is no common occurrence nowadays to see doors of good design and elegant proportion which are unpractical, the lock rail somehow coming too high or too long to enable the handle to be reached easily; as regards the knocker, one has frequently to reach it with a walking-stick or umbrella. Occasionally we find no provision made for the accommodation of the letter-box, which, of course, is a very important article. The usual way out of the difficulty is to see it placed under the side fanlights, or when the latter do not exist, the letter-box is placed on one of the panels as the only solution obtainable without spoiling the proportion of the door with wide rails.

These six- and eight-panelled doors were used internally as well as externally, and were nearly always the pride of the housewife, as the polished smooth surface of the solid mahogany was of beautiful and well-selected

FIG. 2.—DETAILS OF DOOR.

figure. However, these handsome doors were only the property of the rich merchant princes, who imported the hardwoods. The Royal Institute, Colquitt Street, and the Town Hall still have most of their original mahogany doors, of which a detail is given at E, Fig. 2. These doors have the raised panel effect without going to the expense of working down a solid panel, by simply inserting a small mould, which gives the required line and is very effective. The panel mould and little bead on the Town Hall doors are worked in ebony, while those in the Royal Institute are all in mahogany. I believe there still remain two or three of these doors in the old houses, but they are very few in number, as they were generally removed on the departure of the master of the house to a better neighbourhood, where we now frequently find them.

Another kind of internal door we have not yet mentioned is the screen or vestibule door. Of these Liverpool has numerous examples, mostly of simple design, of which a glimpse is obtainable during the milder months, when the front door is thrown back. One of the most elegant forms I have noticed and measured is in a very large house in Hope Street (No. 72, I believe); it is, as usual, a double door opening in two halves (see Fig. 3). The space below the lock rail is panelled, above which it is glazed and divided by small wooden bars of pleasing and elegant form, which might be described as two intersecting stilted circles. Another very common form is to be found in an old china shop in Canning Place, at the corner of Park Lane. As shown by the illustration (Fig. 4), it is formed of straight bars intersecting and producing a diamond kind of pattern; in fact, nearly all the screen doors are based on this last example, being more or less of diamond

form, or squares formed by the bars intersecting one another. The reason why these interesting doors with glazing bars fell into disuse, in the early part of this century, was due to the introduction of plate glass, which immediately afforded the liberty of glazing in large sheets without support. I believe plate glass was first used in Liverpool in a house in Lord Street, about 1820; it was considered a curiosity and was the admiration of the rich, who soon purchased the ugly article.

Of the other old doorways in Liverpool, there still remain many good examples. The pro-cathedral, in Church Street, has four very well-known doors, worked in stone and characteristic of their date—1705. The detail is large and refined, and may be contrasted with our small modern work. There is a tradition about these doors that when this building was erected Liverpool could not boast of a single professional architect, all the work being designed and executed by the master builders, who really developed the so-called Queen Anne style; and as something classic was required an application was made to a London architect to furnish designs for a doorcase, as it was called. He sent down in due course four sketches for the purpose. The authorities here not being able to agree as to which should be selected, it was suggested that the whole four should be adopted, which was accordingly done, and, as may be seen, each of the four is of different design. It appears as if two designs and then two revised sketches were made, as the two on the north side bear great resemblance to the two on the south side, but they are of better proportion.

The doorway illustrated (Fig. 5) is that at the south-west corner, and I might hint that the doors are the work of Wren, Evelyn, or Hawksmoor, as the dates compare favourably with the lives of these men, who were the great architects in London at the time, and the work is not unlike theirs.

The charming group of buildings in School Lane, behind the pro-cathedral, known as the Blue Coat School, has as its main entrance a doorway almost identical with the one on the south-west side, which might suggest the same design was carried out in the two buildings (or else cribbing was in vogue in those days). The date of the door is 1709, five years after the pro-cathedral was erected.

Another dignified doorway with projecting steps belongs to a corner house of York Street and Duke Street (see Fig. 6). It consists of a flight of steps raking with the main front finishing in a broad landing 3ft. 6in. wide, on which the doorway is formed. The iron railing which guarded the approach has disappeared; no doubt it was considered inconvenient for getting boxes and goods in and out, as the house is now a kind of office and warehouse. A little lower down the street, on the other side, a similar doorway (dated 1780) remains with the iron rail complete. It is, beyond all doubt,

FIG. 3.—SCREEN DOOR, HOPE STREET, LIVERPOOL.

FIG. 4.—FRONT DOOR TO OLD CHINA SHOP, CANNING PLACE, LIVERPOOL.

* A paper read before the Liverpool Architectural Society on January 22nd, 1900.

one of the most pleasing old doorways in Liverpool. It is decidedly the work of one of the architects of the epoch, who worked in a more correct and more accurate employment of classic models after Athenian and Roman buildings. They scorned the modest Queen Anne style or the work of the people, though their own work stands out with a conscious architectural effort.

The doorways to the flank wings of the Blue Coat Hospital afford a good example of bold flights of steps projecting 6ft. or 7ft. from the wall face and being about 13ft. wide. The doors and frames are flush with the wall plane, as the fanlights, which are a portion of the window, are constructed out of the same frame as the door; or, in other words, the doors and fanlights, together with the windows, are all treated as part of the wall surface. Contrasting these bold flights of steps, of which we have taken two examples, and of which Duke Street is so full, there are several houses which have a curious form of doorway, which we might describe as Queen Anne open porch. It was formed by setting back the door face 4ft. or 5ft. from the wall plane. The jambs and soffit so formed are panelled or cased-in with wood, and painted white or cream, the colour of the period.

This porch effect produces a fine shadow and relieves the flatness of the elevation, and suggests several ideas as to its origin. The first thing that strikes one on seeing these doorways is that the old men were tied down to very strict frontage lines and were not allowed to have projecting flights of steps as we still see in streets built before the Act or by-law came into force. Well, rather than be beaten by the town's surveyor (in fact the old men never were beaten by any difficulty) and lose their grand flights of steps, they recessed their doors and therein placed the steps, so avoiding setting back the building. Another idea seems to have been to get a porch effect which would afford shelter to their welcome callers, or the beggar, from the driving rains and cold winds. These doors were as a rule very plain and flat as regards the wall treatment, having simply an architrave and cornice at the top.

Before passing on to fanlights, one word about door furniture, such as knockers. Nearly all the old knockers are gone from their original homes, like their masters, but occasionally we find one or two as mute reminders

of their former pomp, pride, and importance. We have heard of the whole side of a street being divested of its knockers in one night, probably on account of the value of the metal, as many were made of solid brass. In London a brass knocker and a high doorstep were considered in those days as an outward and visible sign of a boarding-house or an aggressive family. That is why so few are found in the West End.

Fanlights were nearly always moulded in cast-iron or lead when of intricate design, no doubt on account of the difficulty of constructing them in wood; in fact, they look what they are, and no attempt seems to have been taken to mask

the material by imitating wooden designs. Some of the fanlights were considered so valuable that we hear of them being insured against breakage in riots, &c. The fanlight to the house in York Street is plain and simple (Fig. 6). Wolstenholm Square, which very few people know, as it is surrounded by warehouses, has a large fanlight of good and manly design; in all probability 26, Duke Street, had the same as indicated by dotted lines in Fig. 1. The old china shop in Canning Place has a common form which belongs to that kind of door (Fig. 4).

Now we might take a few practical details which may be suggestive and help to give a little interest to the too often plain door. The first detail (A, Fig. 7) is a small mould, let into the stile and returned round the top and bottom rails, which was often done by Wren, and it gives the door a look of unity amongst its panels, as they are all connected.

Something similar is shown at B (Fig. 7), in a cheaper manner; it can be obtained by designing the panel mould into two orders, so to speak, using the first order for the muntins only and the two orders for the stiles and rails. It gives an interest to the door and pulls the design together. Another interesting detail (C, Fig. 7), and a great favourite with Mr. Norman Shaw, in his large houses, is to mould the stiles, top and bottom rails. The effect is rich, but costly. This detail is very common amongst Scottish woodwork. Another simple treatment (D, Fig. 2) to external doors or gates is to enclose the panel with a large bolection mould on the top and two sides, letting it die on to a kind of sill at the bottom. This is very suggestive and also very practical for doors exposed to the weather, as the sill throws off the rain.

As we have touched on keeping out the driving rain, a very common place for it to enter is on the top step. The simplest way to avoid this is to keep the door and the top step in the same plane, and if the site is exposed, to insert a moulded sill to throw off the water (see H, Fig. 2). A very useful detail for front doors that are nearly always opened back, such as in offices, is not to hang the door to the usual rebated frame, but simply to a square frame (see G, Fig. 2). When the door is open the frame and door are on the same face and the effect of panelling is produced. Of course the back of the door is ugly and has an unfinished appearance and this detail is only suitable for doors seen only on the outside and always open.

FIG. 6.—MAIN DOORWAY TO A HOUSE AT THE CORNER OF YORK AND DUKE STREETS, LIVERPOOL

FIG. 5.—SOUTH-WEST DOOR, PRO-CATHEDRAL, LIVERPOOL. DRAWN BY M. HONAN.

FIG. 7.—DETAILS OF DOORS.

Just another detail (F, Fig. 7) and that is to hang internal doors to an architrave so as to expose both sides of ornamental steel hinges, when one desires to use them.

MR. JOHN BELCHER.

THE NEW A.R.A.

THE election of Mr. John Belcher to the Associateship of the Royal Academy is a fitting recognition of an industrious career and many distinguished accomplishments in the architectural world. The general feeling of the profession will be, we feel sure, that the honour could fall to no more deserving recipient. A few particulars of Mr. Belcher's professional career will be read with special interest at the present time.

Articled to his father, Mr. Belcher brought to this beginning of his career the knowledge he had gained as a boy in Paris, where he had been sent to study and sketch, with parental instructions to pay especial attention to the Renaissance, as understood in France. For some years after this he worked in partnership with his father; but, when the latter retired, John Belcher, to quote his own words, "after swallowing Street's Academy lectures, forthwith proceeded on a wild Gothic career."

Before, however, he had ranged through the Gothic styles, to come back at last to Classicism and the Later Renaissance, Mr. Belcher found Nuremberg and Rothenburg,

and the old cities of Germany, full of inspiration; and if he had not at a later date visited Italy and become impressed, as one needs must, with the Renaissance works of Florence and Pisa, he had never, we may safely assume, given us such a work as the building for the Institute of Chartered Accountants.

When Mr. Belcher designed the new buildings for Messrs. Rylands and Sons after the great Wood Street fire about eighteen years ago, they were, with a due regard for the requirements of private firms for lavish decorations, done in the Dutch convention of the sixteenth and seventeenth centuries. The wonderful invention and fertility of resource of those old Hollanders were then exercising an influence over Mr. Belcher's design, and he was passing through a period of enthusiasm in which the old merchants' houses that front the now silent waterways of Dordrecht, Haarlem, and other decayed cities of the Netherlands, seemed most desirable starting points towards designs for business premises in living London.

He has produced many works which mark a gradual development from the picturesqueness which then meant so much to him onward to the chastened severity of his later years. One cannot, without difficulty, hope to follow him here in restorations of village churches in Warwickshire and Wilts; but it is in his designs for country houses that one finds much work of an interesting quality. Most of these houses are done in what one may perhaps be allowed to call a Tudor convention: Holcombe, near Chatham; Yeldhall Manor, near Twyford, originally named "Bearroc"; houses at Henley; houses on Chiswick Mall; Mark Ash,

Surrey; and his own house, "Redholm," Champion Hill (of which we give an illustration); stables and studios, Brenchley; house at Royston; cottage hospitals, Norwood and Chatham; and many others. A later development may be observed in such houses as Morden Grange, Blackheath, additions to Court Lodge, Boxley, to Dr. Gandy's house, to that of Mr. De Chapeaurouge, Norwood. The alterations and additions for the Earl of Eldon at Stowell Park are on a very large and important scale, comprising some entirely new works and the remodelling of old buildings which hitherto have had no outstanding architectural character. Terraced gardens, new stabling, and laundry buildings are included in these works. The gardens of Stowell Park, and many of his houses, have been specially designed by Mr. Belcher. This is a matter which he feels to be of great importance, as it enabled him to link the building with the site, throwing out tendrils in the shape of terraces, walls, and hedges to tie it to the ground.

But, so far, the most interesting of all Mr. Belcher's works is the building for the Institute of Chartered Accountants, with those happily

JOHN BELCHER, A.R.A., F.R.I.B.A.

"REDHOLM," CHAMPION HILL, S.E.: MR. BELCHER'S

allied features, the decorative friezes of sculpture along the elevations by Mr. Hamo Thornycroft, R.A., and the sculptured figures by the late Mr. Harry Bates, A.R.A.

We regard this building, Mr. Belcher's dignified design for the completion of the South Kensington Museum, and that for the Colchester Town Hall, and the Cambridge Guildhall, as contributions towards the formation of a style in these days when architects have been content for the most part to borrow from the work of the past. Already we may see from the works of his imitators, in which attenuated entablatures, engaged columns, deep sculptured bands about the middle of buildings, and heavily rusticated ground-floor piers are reproduced with a touching fidelity, if sometimes also with exasperating want of fitness, that he has made a considerable impression upon the art of his time. All this is an unconscious tribute to the influence Mr. Belcher's work has upon the minds of some of the younger men.

It is obvious to the observant eye that the desire for the attainment of restfulness, solidity, sternness, and soberness, underlies Mr. Belcher's work, despite the hindrances of the building system; despite the thousand and one obstacles that lie in the way of the modern architect, blunting the edge of the keenest idea. It is not a small achievement to have done this, and the slightest advance is a great one in an age of marking time.

HERALDRY.—III.

By GUY CADOGAN ROTHERY.

(Continued from page 386, No. CCLIX.)

HONOURABLE ORDINARIES AND SUB-ORDINARIES.

AS stated in the first chapter, the early ornamentations, or charges in heraldry, were merely the strengthenings of the shields. These are generally held, by the most competent of the old heraldic authorities, to be ten in number, and are termed honourable ordinaries.

As these ordinaries already existed on the escutcheons of the principal nobles, and, indeed, on nearly all of the earlier coats of arms, the heralds who were appointed for the purpose of introducing a little order and method in the science classed them as the first and highest order of heraldic charges. It is hardly astonishing to find that nearly every one of these ten different charges has a special meaning or legends attached to it.

One of the greatest contrasts between English and Continental heraldry is that our heralds attach a particular value to the escutcheon according to its simplicity, as the escutcheons of the younger branches of a family often had new additions to distinguish them from the elder branch. On the Continent the escutcheon is valued by the number of charges, in many cases the ordinaries as well as the field being heavily charged. In English heraldry it is allowable to emblazon the honourable ordinaries with almost any common or minor charge, but the practice is not so much resorted to as on the Continent.

The principal ordinary is the *chief*; it occupies the upper part of the shield, divided from the lower by an horizontal line, which ought to fill up one-third of the surface of the field.

Each ordinary has a certain number of diminutions, or modifications of the parent charge. In the case of the *chief*, its diminutive is the *fillet*, one-fourth of the chief, and is always placed in the lower portion of the chief.

The *pale*, second in importance, is a band, occupying one-third of the shield, from top to bottom. Its diminutives are the *pallet*, half the size of the *pale*, and the *endorse*, which is half the size of the *pallet*.* The word *endorse* comes from the French *endosé*, to place back to back; a *pale* when emblazoned between two *endorse*s is said to be *endorsed* or *indorsed*.

The *bend* represents a band, one-third of the shield, crossing from the dexter chief to the sinister base. The *bend* has three diminutives; they are the *bendlet* (sometimes called a *garter*), the *cotice*, and the *ribbon*. A shield divided into several parts by lines in *bend* is said to be *coticé*.

* In every case the first diminutive ought to be one-half of its parent charge, the second one-half of the first, the third one-half of the second. This rule does not apply to the chief, the cross, the saltire, or the quarter.

THE CHIEF.

The *bend sinister* is the *bend*, or *bend dexter*, reversed, coming from the sinister chief to the dexter base. The *scarpe* and the *baton* are its diminutives. The *baton*, variously called *baton* or *batoon*, is the charge used by heralds as the mark of bastardy.* It is sometimes borne *coupé* when its extremities do not touch the sides of the shield. This was a special privilege, and at one time but rarely conceded. Another mode of lessening the disgrace of this charge was to have it reversed, a privilege conferred only on extraordinary cases. After the bravery displayed on the battlefield against the English by John the Bastard of Orleans, Charles VII. allowed him to turn his *baton* from sinister to dexter. A like boon was granted to the Earl of Murray by his sister, Queen Mary of Scots.

The *fess* is an horizontal band in the middle of the shield, and occupies one-third of its surface. It represents the waist-band, one of the symbols of knighthood or high military command; the officers' and non-commissioned officers' scarves, still worn in our army, are relics of this ancient scarf of authority. The *bar*, the *closet*, and the *barrulet*, this last always borne in couples, are the diminutives of this charge.

The *chevron* is formed by two bands rising from the sides of the shield and meeting in a point in the centre. It is one of the charges formerly given to founders of families, and is highly prized. A *chevron* is sometimes borne *rompu*. The diminutives are the *chevronel* and the *couple-close*, which last is always borne in couples and often one on each side of the chevron, when the chevron is said to be *couple-closed*. Many heralds hold that the chevron represents the principal rafters of a gable roof, to which the term still applies in the French language, and hence is an appropriate charge for the founders of a family; another

* The term *bastard bar* has been popularly, but erroneously, given to this symbol; the *bar* is a diminutive of the *fess*, and therefore the term *bar* cannot be applied to the diminutive of the *bend sinister*.

THE PALE.

theory is that it symbolically represents a park gate.

The *cross* is a combination of the *pale* and the *fess*; it is a favourite and much-valued charge. The ornamentation of heraldic crosses is extraordinarily varied; this "honourable ordinary" is deserving of a treatise by itself. The principal crosses are the plain cross; the cross crosslet, a cross with the limbs having a transverse bar near the ends; the cross pattée; the cross moline; the cross fleury, or ornamented at each end with fleur-de-lis; and the cross patonce.

The *saltire* is formed by *bend dexter* and *bend sinister* conjoined.

The *pile* is in the form of a wedge, the point downwards. Its proper size is one-third of the shield in its upper part, but if it is charged its broadest end fills up two-thirds of the shield. A *pile* may be borne *transposed*, that is to say, with the point uppermost.

The tenth and last "honourable ordinary" is the *quarter*, which occupies the upper dexter position of the shield, consisting of one-fourth of its surface. It has one diminutive, the *canton*, occupying one-eighth of the shield.

All the above charges may be *voided*, a term applied to a charge when it has its centre removed, showing the field through it. The *voiding* may be of any shape; a cross is voided *per-pale*, or *per-fess*; but in such a case the shape of the *voiding* must be specially mentioned, otherwise it would mean that the charge was *voided* of its own shape. Mr. Mark A. Lower, the author of "Curiosities of Heraldry," says that this curious custom of *voiding* was adopted because the bearers had lost their patrimonies, and retained only the shadow of their ancient greatness.

The terms *in pale*, *in bend*, &c., when applied to common charges, denote that they are borne disposed in the form of the ordinary mentioned. A shield is said to be *paly*, *bendy*, &c., when it is divided by several lines in the form of the ordinary mentioned, the number of divisions

THE BEND.

THE BEND SINISTER.

THE FESS.

being also specified with the tinctures; the first division being of the first-mentioned tincture, the second of the second, and so on alternately. A shield may be divided *per-pale*, *per-bend*, &c., when it is of two different tinctures and divided in the shape of the ordinary. A common occurrence in heraldry is to have the charge and the field *counter-changed*, a term employed to denote a party-coloured charge displayed on a party-coloured shield, half metal and half colour, of the same tinctures as the charge, which has its metal part on the colour and the coloured part on the metal of the shield. The term *tierced* is applied to a shield which is divided into three parts; it may be either *tierced in fess*, *in pale*, *in bend*, *in bend sinister*, or *in pale*, according to the form of the three parts.

When any ordinary is pierced by a square hole, it is said to be *square-pierced*; but if, in the case of a cross, the whole of the intersecting portion is removed it is termed a *cross quarterly-pierced*. Ordinaries may be simply *pierced*, i.e., pierced with a round hole, and also *lozenge-pierced*; they are often borne *couped*, that is to say, they have their extremities cut off and so do not touch the sides of the shield; they may also be *rompu*, when the ends instead of being cut off with a smooth edge are torn off and present a ragged edge.

THE SALTIRE.

THE CHEVRON.

shield is covered with lattice-work it is termed *fretty*, or *fretty cloué*, when, instead of being interlaced, the dexter lattice is placed over the sinister bars and nailed.

The *bordure* is a broad band encircling the

THE PILE.

shield; it is sometimes, although seldom, charged with common charges, and, therefore, has been, by some heralds, enumerated with the honourable ordinaries.

Its diminutives are the *crle*, which, unlike the *bordure*, does not touch the edges of the shield; and the *tressure*, which is generally borne *flory-counter-flory*. Both of these are by some heralds classed as distinct charges, and not as diminutives of the *bordure*. The *tressure* in Scotland is most highly esteemed, it being a royal charge, encircling the red lion of the Scottish arms, and was only granted to private individuals by a royal warrant, and then only in cases where the recipient had

THE CROSS.

performed some great deed for the good of his sovereign or country. It was also granted to the families directly descended from the female members of the royal family.

The *pall*, an ecclesiastical vestment and ornament, is a combination of the upper part of the saltire and the lower part of the pale.

The *flanches* are the dexters and sinister portions of the shield when they are cut off from the rest by curved lines; they are always borne in pairs, and the fact of their sometimes being charged has made some authorities class them as honourable ordinaries. The *lozenge* has four sides, the upper and lower points acute, and the side ones obtuse. Its diminutives are the *rustre*, or lozenge with a round hole through the centre (when the hole is square it is termed *square-pierced*); the *fusil*, which has its upper and lower angles much more acute than the *lozenge*; and the *mascle*, a lozenge showing only a narrow rim, through which the field is seen. The *mascle* probably was intended to represent a link of chain armour.

Among some of the most ancient charges are the *roundels*, small circular charges, which are sometimes classed as sub-ordinaries. *Roundels* are called *bezants* when of or; when they are tintured argent, *plates*; gule, *torteaux*; azure, *hurts*; sable, *ogress* or *pellets*; vert, *pommes*; purple, *golpes*; sanguine, *guzes*; tenné, *oranges*. The *plate* is sometimes borne barry of seven argent and azure, when it is called a *fountain*.

The *mullet* and *star* have sometimes been classed among the sub-ordinaries. The *mullet* is a charge representing a spur-rowel, and has five points. The *star* has six points or more; they are always *wavy*, but, if it has more than six points, only every other one should be represented as *wavy*. The *mullet* and *star* were respectively military and ecclesiastical charges.

Flames of fire, when borne alone, may be counted as sub-ordinaries. They are borne as

THE QUARTER.

THE GYRON.

THE FRET.

THE FRET.

symbols of the bravery and valour of the original bearer, ever impatient to lift his eyes and thoughts upwards; always thinking of and aspiring to perform, and no doubt sometimes having accomplished, brave deeds. The charge is often seen on the Continent. Fire-bombs, fire-buckets, fire beacons, and torches in flames are of more frequent occurrence, but these cannot be classed as sub-ordinaries; they belong to the vast number of common charges.

THE LOZENGE.

Then there is a curious device known as the gurge or gorge, which is intended to represent a whirlpool; it occupies the whole of the shield. Its tinctures, when borne proper, are argent and azure; if it is of any other colours it should be mentioned.

A shield may be divided *per-pale*, *per-bend*, &c., but these lines of division are not always smooth. The principal lines of division are: *wavy*, *engrailed*, *invected*, *indented*, *dancette*, *nebulé*, *embattled*, *dovetailed*, and *potentée* (see page 351, No. CCLVII).

INESCUTCHEON.

THE FLANCHES.

THE TRENT EMBANKMENT, NOTTINGHAM.

THE construction of the new Trent embankment, at Nottingham, is being vigorously pushed forward. The object is to form a broad road, or drive, combined with a fine promenade, alongside the Trent, extending from Trent Bridge to Wilford Bridge, a distance of a mile and a quarter. The first pile was driven in May, 1898, and now the whole of the piling has been completed, and about nine-tenths of the filling up necessary to raise the whole of the road several feet above the river level has also been accomplished. All the material required for the raising of the embankment has been obtained by dredging gravel from the river. This method has not only been the means of saving considerable trouble and expense, but it also possesses the important advantage of materially deepening the bed of the river at the same time. So far, no less than 250,000 tons of gravel, &c., have been taken out of the river. Unfortunately, progress has been somewhat delayed in consequence of the rock in several places being within 2ft. or 3ft. of the level of the water, necessitating the suspension of dredging operations until the rock was blasted away.

Rising from the water are tiers of concrete steps, which may, in fine weather, afford seating accommodation, and will yield exceptional facilities to boatmen and anglers. Next to the steps comes—what the æsthetic eye could well have spared—a hauling path, but this, though little required, has to be maintained for navigation purposes. The work of kerbing and ballasting is being proceeded with as rapidly as materials can be obtained. The foreshore, which will be some yards in width, is now being turfed. The carriage drive will be 36ft. wide, and on either side, separated from it by grass and tree-planted verges, is to be a footpath, that nearest the foreshore being 15ft. wide. The total span of the road, including footpaths and grass verges, will be about 90ft., or half as wide again as the Lenton Boulevard. Both the Corporation and the owners of the Clifton estate, who between them own the whole of the property abutting on the new embankment, are reserving the land until the completion of the work, when it is expected to realise high prices as sites for villa residences. A large staff of men is employed upon laying and turfing the slopes and planting trees, of which there are to be three rows. At present, with thousands of tons of material lying about, with carts churning up the mud on the banks, and with unsightly dredgers in the river, the scene is not a prepossessing one. Nevertheless, order is being slowly evolved out of chaos, and, as the summer approaches, clearer evidence of the nature of the work will be forthcoming. When the scheme has reached its full extent, with trees in leafage, green turf, and handsome riverside residences—naturally a process not capable of completion in a year or two—it can be said, without boasting, that the city will possess a riverside

promenade second to none in the country. No heavy traffic will be allowed on the road at all. A suggestion has been made that the central avenue of Queen's-walk should be turned into a drive, so that a complete circuit could be made and the embankment reached by vehicles without the necessity of going round by Wilford-road. In conclusion, it should be stated that the work has been designed, and is being carried out, by Mr. Arthur Brown, the city engineer.

Correspondence.

Messrs. Sax's Calendar.

To the Editor of 'THE BUILDERS' JOURNAL.

LONDON, S.E.

SIR,—Our attention has been called to an editorial note in your issue of January 31st, in which you quote a letter from a correspondent expressing annoyance that his request for a copy of our 1900 calendar was not complied with by us, and complaining that we asked him to send us a "trade card." We cannot think, however, that your correspondent quoted the whole of our letter to you, and in order to clear ourselves in your eyes from the charge of discourtesy which would seem to be implied, we venture to point out that our sole reason for confining ourselves to members of the trade was that, owing to the rush for these calendars, which, we must admit, entirely exceeded our calculations, it was quite impossible for us to comply with the hundreds of requests which we have received; and since some of them had to be disappointed we thought that, being engaged in the trade supply business, it was only fair that we should give trade applicants the preference. Trusting that this explanation will be satisfactory to yourself, and to any readers of your journal who, on the strength of your remarks on our calendar, made application for the same and have not yet received a copy,—We are, dear Sir, your faithfully,

JULIUS SAX and CO., LTD.

The Study of the Human Form and its Influence on Architecture.

To the Editor of 'THE BUILDERS' JOURNAL.

LONDON, E.C.

SIR,—Mr. Jemmett's idealism is deducible from his writing, and that he has written, at "white heat," a rhapsody on the beauty of the human form is evidenced by your columns. But is the beauty of the human form so new a discovery that it requires promulgation or support in this nineteenth (or twentieth) century? The title of the article engendered a hope that Mr. Jemmett would attempt graver work, would show how the human form and architecture were knit and wed together, indicating a path of learning the student might tread till he arrived at the ability to place the human form on a building without destroying the beauty of the former or the architecture of the latter. But in this regard, the worst defect of English design, Mr. Jemmett's pen has not moved. Your author, too, is most unhappy in his comparisons, as anyone must be who attempts to contrast "a thing Divinely fashioned" with the labour of human beings. Such comparisons are always odious, but they need not be ridiculous. If you must compare, at least choose something similar in action or function. What is the function of an iron column or joist? Roughly, the carriage or support of a permanent weight; that is its sole purpose. Does Mr. Jemmett contend that this is the sole purpose of the human form? Possibly, if he had watched the moving machinery of an ocean liner, he might have found a better simile to his purpose, and if he had studied Kipling to the extent of "The ship that found herself," or "McAndrew's Hymn," he would understand how even an inartistic intelligence can see in the rush and thrust of the levers, not only beauty and perfection, but the presence of a soul.—Yours faithfully,

CIVIL ENGINEER.

R.I.B.A.

A MEETING of the Royal Institute of British Architects was held on Monday evening last, when the president (Mr. William Emerson) occupied the chair. Mr. Alexander Graham expressed regret at the death of Mr. William White (who was elected a Fellow in 1859) and it was resolved to send a letter of condolence to his relatives. The president then announced that it was the Council's intention to submit the name of Professor Rodolfo Lanciani to Her Majesty the Queen as the recipient of the Royal Gold Medal for 1900. Professor Lanciani is a great archaeologist and topographer and has contributed very largely to our knowledge of Ancient Rome, about which he has written a great deal. He received the Queen's Gold Medal in 1849, more particularly for his work "The Edifices of Ancient Rome," and is an honorary corresponding member of the Institute.

The President's Address

to students was full of interest, and the following is a synopsis of it:—

The practice of architecture is quite one of the most toilsome and difficult, as well as one of the most noble, worthy and interesting of all secular pursuits, and one in which the life and history of a people should be indicated more than in any other. To enter upon it is, therefore, a very serious step for a young man to take. Architecture is not solely a fine art, nor is it altogether simply a profession. It has two distinct sides. The one is the artistic side, the other the practical and business side, and both are as essential to each other as the stomach to the head. For instance, without a certain amount of legal knowledge an architect cannot safely advise his employers regarding contracts with builders, or in respect to the purchase of or dealing with building sites. There must also be a knowledge of the latest scientific inventions affecting buildings, of construction in all its details; materials, accounts, and the values of materials and labour. But apart from all the practical matters, and to turn to the artistic side, a wide appreciation of the beautiful in all styles of architecture is necessary for the enlargement of the views, and to open the eyes as to what architecture in its highest aspirations really means.

The practice of architecture *should not mean* to those adopting it just a means of livelihood. Were this the idea bad builders might be evolved, but never good architects. It *should mean* the putting of selfish ends on one side for the sake of the art, with a determination that no personal considerations shall weigh in the balance, providing in the best manner for our employer's wants at any amount of self-sacrifice, and building for them in truth and beauty, to the utmost that may be in the capacity of the architect. Further, it should also mean, building not just for the present, but for the future, works that may last, and of such a class that future generations may form a high, and not a low, opinion of what we are as a nation. To arrive at this altruistic level of work means an exalted feeling of the value to others of beautiful architecture, and the worth to the world of honest hard work.

There are several things most necessary for the student who has such high aims. First, there must be diligent study. Second, there must be the power of drawing. Third, there must be enthusiasm. And with all these there must be combined a high ideal of the responsibilities of the architect. Then, granted that you possess all these gifts, if you have not the *spirit* of architecture you had much better leave it entirely alone; for if under the circumstances architecture paid you, you would derive no sort of satisfaction from it but the monetary one, and that can be obtained with less exhaustive labour in inferior occupations.

With regard to study, if you do not consider Greek work you will not understand Roman; if you ignore Roman half the meaning of Romanesque and Byzantine will be an enigma to you. Unless you have studied all these thoughtfully you will really know but little. Therefore study all styles of architecture, and

that without prejudice; but the best of the various styles and their purest examples should be the subjects of the first most careful study, reflection, and comparison by the student. The finest works in architecture are those which have perfectly suited the circumstances of the age and nation for which they were erected, were well and honestly constructed, stately and beautiful in proportion and detail, and truthful in the expression of their purpose. And the best examples are those which are the purest, whether in Greek, Roman, Gothic, Renaissance, or any other period.

Some time ago the one thing most prominently urged upon students of architecture was the paramount necessity for draughtsmanship, drawing first, drawing second, and drawing last. This resulted in much good, and draughtsmanship has now been brought by many of you to a high pitch of excellence, but also, I think, some harm has resulted. Too great value seems occasionally attached to the effect, technique, and execution of the drawing itself; and the quality of the architecture, a far greater thing, is sometimes apparently considered of secondary importance. This is entirely wrong. The effect of architecture certainly cannot be shown without good drawing, but draughtsmanship, however excellent, cannot make inferior architecture good. French drawings of architecture are much more academic than ours. I think our style of drawing is defective in many ways. French drawings give by clean lines and properly cast shadows a fairly truthful impression of the detail, relief, and projections of a building. By our method shadows are sketched in merely with a view to look pleasing on paper, and frequently convey a false effect of the cornices and other salient features.

Some years ago designs were mainly shown by coloured perspectives; then it was said they were so faked up by the artists that they were quite untrue representations of the designs. Consequently pen and ink drawings became the fashion. But I would ask what can be more untruthful and misleading than a black and white line drawing of a building constructed of several differently coloured materials? A monotone design, no doubt, can be well shown this way, but is it not evident how misleading an etched drawing may be in representing, for instance, a design in red bricks and white stone?

Therefore, learn to draw accurately and definitely, as many of you already do excellently well, but do not neglect to supplement it by careful dissection and measurements. Also study the human figure, for more than all else that instils a fine sense of proportion. But, above all, do not let sketching run away with you, or mistake drawing for architecture; it is not; but simply a means to an end, and bears the same relation to it that an alphabet bears to a language.

The third essential I would put before you as imperative to the successful accomplishment of noble architecture is an unlimited enthusiasm. If you look towards the sun your own shadow is unseen, being cast behind you; so if your mind's aspirations are steadfast towards a lofty ideal, through your entire possession by this God-inspiring zeal, there will be complete unconsciousness of self in respect to your art.

Further, it is all very well to fancy, as some appear to do, that architecture as a fine art is altogether apart from, and above, the sphere of such practical matters as drainage, heating and ventilating, electricity, hydraulic power, gas and water supplies, and suchlike. Granted that it is on a higher level, nevertheless there is no important edifice, public or private, erected now, to which these things are not vital; it has been well said they are the very nerves of the structure. If any building is to properly answer to its requirements it must be not only artistic, but also scientific.

Let noble architecture be your first consideration, but practical use should follow closely in the wake. The true architect must ever aim at the highest ideal, if his work is to live; but always let your ideal be beyond your best efforts.

In conclusion, I will leave with you the

following words as worthy of thought, for without some such sense of moral responsibility as is implied in them your work in life as architects or men will be deficient in quality: "Our task in this life is to employ to the uttermost that human faculty, that human talent which has been given to us, and not to let it wait for some exceptional moment in which we shall probably never find ourselves, or we may die without ever knowing or dreaming what lies in the capacity of everyone of us to be, to dare, or to do."

Mr. Bodley's Remarks.

Mr. G. F. Bodley, A.R.A., followed the President with a light criticism of the Institute designs, and afterwards enlarged into a very able discourse on many vital matters affecting architecture. The drawings submitted for the Owen Jones studentship were, in his opinion, almost without exception, very carefully done, and, this prize dealing with colour, he emphasised what an important factor colour was. It was one of the fairest of the hand-maidens of architecture, but it ought always to be treated with breadth of effect. With regard to marbles, the employment of two kinds gave the best result. Architects of the present day were too prone to use many kinds of marble in their work. The Pugin drawings he considered very satisfactory. He, however, did not think it much good to criticise drawings. Theirs was not a drawing school; it was a school of architects. Drawing was not design, and they drew but poorly when they built magnificently. The Tite drawings did not altogether please him; he missed a charm about them, and there seemed to be wanting more idea and greater consideration and more freedom in design. Mr. Varndell's drawings for the Grissell prize were boldly and carefully delineated, and he was also pleased with those by "Tiny." He was glad that the medal had been given to Mr. Fulton for his measured drawings of St. John's College, Oxford; but as to the Soane designs, he felt that something better might have been done. Having made these rapid criticisms, he dwelt on the chief principles in architectural design. First, there was refinement of design and detail, which was often sadly lacking in present-day architecture. Everything ought to have real life in it, and whatever was the expression of death was bad. Refinement of design gave this life. Next, there was concentration of ornament. For the enjoyment of ornament there should be a concentration of it, rather than a sprinkling over the whole edifice. Thirdly, came the true use of detail. It was a great error to suppose that by enlarging the detail you made the building look large. The reverse was eminently the case. Symmetry or balance was the fourth principle, and then came economy of material as a part of refinement. Good architecture was not only building to stand, but building to last. Strength combined with economy should be our aim. As regarded breadth contrasted with detail, the fifth requirement, he pointed out how in Gothic ornament the delicate lines of light on the ridges, and the sudden deepening and darkening of the background, set off the design. Sixthly, he urged suitability in buildings, and said that the architect ought to build according to his surroundings, and in contrast or harmony with them, and in this connection he pointed out that there was no need for us to go abroad for models; our own English architecture was second to none for poetry and beauty. We might have patriotism in art. Lastly, there was harmony and character and feeling in the same building, and, in his opinion, no eclectic school which mixed styles would live long. A vote of thanks to the President and Mr. Bodley was proposed by Sir James Linton, seconded by Mr. H. Axel Haig, and carried unanimously.—The prizes were then presented.

Liverpool Church Destroyed by Fire.—

St. Saviour's Church in Huskisson Street, Liverpool, was destroyed by fire on Sunday last. The outbreak is attributed to a defective flue.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"There are two characters in which all greatness of Art consists—first, the earnest and intense seizing of natural facts; then the ordering those facts by strength of human intellect, so as to make them, for all who look upon them, to the utmost serviceable, memorable, and beautiful. And thus great art is nothing else than the type of strong and noble life; for as the ignoble person, in his dealings with all that occurs in the world about him, first sees nothing clearly, looks nothing fairly in the face, and then allows himself to be swept away by the trampling torrent and unescapable force of the things that he would not foresee and could not understand: so the noble person, looking the facts of the world full in the face, and fathoming them with deep faculty, then deals with them in unalarmed intelligence and unhurried strength, and becomes, with his human intellect and will, no unconscious nor insignificant agent in consummating their good and restraining their evil."—RUSKIN.

Extra-ordinary.

DURING the last few weeks hundreds of in memoriam notices of John Ruskin have appeared in the public press, practically all expressing real appreciation of his life-work. We have received one from a Liverpool correspondent, who fittingly signs himself "Original." We print it as a curiosity. The following key is, however, necessary to the understanding of the symbols used:—Margin black line, life's span from birth to age; circle at top, eternity; circle with bar, emblem of Grand Architect; bar below date, Egyptian Met gauge or span of life; AO, alpha and omega.

Silence!!

Man's head is bent;
Forest flowers crystal tears shed;
Hearts ing'le spark bath sped:
Art's temple veil rent,
Muffle bells, Anthem Requiem,
England has lost the Great Poet,
Artist, Philosopher, King—
John Ruskin.

1900
A

The New Royal Academicians.

ON page 390 of our issue for January 24th last, we hinted that the probable successful candidates for the three vacancies at the Royal Academy would be Mr. Belcher, Mr. Farquharson, and either Mr. Pomeroy or Mr. Drury. The result of last week's elections is that Mr. Belcher, Mr. Drury, and Mr. H. S. Tuke were added to the list of associates. In the first election, it is stated, those who received sufficient "scratches" to have their names inscribed upon the blackboard were Mr. Farquharson (16), Mr. Tuke (15), Mr. Edward Stott (10), Mr. Yeend King (4), Mr. George Simonds (4), Mr. Ridley Corbett (3), and Mr. Belcher (3). The ballot between the two first-named brought in Mr. Tuke by no less a majority than 23, he receiving 40 votes to Mr. Farquharson's 17. In the second round Mr. Farquharson was still a prime favourite. In the first "scratching" he obtained first place with 15 votes, while Mr. Belcher, received 13, Mr. Stott 11, Mr. Simpson (the architect) 9, Mr. Simonds 5, and Mr. A. Drury 4. In the ballot Mr. Belcher obtained 29 votes to 28 cast for Mr. Farquharson, who for at least the second time in the last few years has been shut out from the Academy by only one vote. The third round was now entered on, and only four amongst the fourteen voted for succeeded in getting on the blackboard. Mr. Alfred Drury received 20 votes, Mr. Farquharson 19, Mr. Stott 12, and Mr. Simonds 4, and in the

ballot Mr. Drury won by 33 votes to Mr. Farquharson's 23. The Academy has thus taken to itself an extremely capable painter of the new school, an architect renowned for the excellence of his designs, and a sculptor whose training with Monsieur Dalon has filled him with the best traditions of the French school. We give on page 5 of this issue some particulars of the career and work of Mr. Belcher.

Doors and Fire.

WE have received from the British Fire Prevention Committee Nos. 35 and 39 of their publications, both dealing with doors. The former gives details of a test made with a 2in. framed pitch-pine door and a 2in. framed deal door, in which honours were about equally divided. We gave some further details of this test, which was made in October last, on page 184 of our issue for October 25th. The doors dealt with in the test described in publication No. 39 were a 2in. framed Honduras mahogany one, with 2in. solid panels, and a 2in. framed poplar door, also with 2in. solid panels. In 1 minute smoke came through the joint between the head of the poplar door and the frame; in 5 minutes the flame through this joint became continuous; in 10 minutes the door was much twisted, and flame came through the joint at the top, and part of the way down the sides; then, after 15 minutes, a slight spurt of flame appeared between the frame and the top of the mahogany door; in 24 minutes one of the top panels of the poplar door fell in; in 26 minutes the flame at the top of the mahogany door became continuous all along the top rail; in 36 minutes the whole of the poplar door had collapsed and fallen in; in 42 minutes flame appeared through the joints of the four outer corners of the lower panels and bottom outside corners of the upper panels of the mahogany door; and in 49 minutes this door fell inwards, all the bolts and hinges being red-hot, and becoming detached from the door. It will thus be seen that the mahogany door stood for nearly a quarter of an hour after the poplar door had collapsed.

Pinnacles Out of Plumb.

WRITING to a local newspaper with regard to stone pinnacles out of the upright, Mr. Harry Hems, of Exeter, says: "They were never built so purposely, any more than was the (very ugly, to my mind) celebrated circular leaning tower at Pisa, or the even more perilous looking pair of square watch towers at Bologna. The sun has an effect upon soft stone, and I should conclude the pinnacles alluded to have been drawn over by the sun's rays, precisely as may be seen on a larger scale in the bent spire that crowns the western tower of St. Peter's fifteenth century church at Ermington, in this county. I recollect that thirty odd years ago every pinnacle (all built of Beer stone) upon and about the roof of Exeter Cathedral curved over one way, drawn towards the sun. They have all one by one been removed, and new ones substituted since then. The quaint south-east spire of SS. Peter and Paul, Barnstaple, built of oak covered with lead, got twisted as it now is during a thunderstorm. The celebrated and unique tall spire at Chesterfield parish church, Derbyshire, takes a hoist three distinct times between the tower battlements and the weather vane. It was originally built of green oak not properly seasoned. This was covered with lead, and when the hot days came the air within got so warm that the sturdy English oak (the stubbornest wood in the world) got awry, and hence its present ugly lines. We see the same thing on a smaller scale done every day when an oak lectern is placed over a hot-air grating. And larger things than lecterns—goodly-sized pulpits—suffer sometimes from the effects of hot air."

Casting for Plaster Models.

MR. AUGUSTUS SIMSION, who is a model caster, carrying on business in Denmark Place, Charing Cross Road, and Mr. Henry Fehr, a sculptor, who has a studio in Fulham Road, recently entered on a transaction which ended in the High Court. Mr. Simsion's claim was for £62 for casting a

plaster model in bronze. The defendant counterclaimed £250 for damages done to the model. The plaintiff had made for the defendant two bronze griffins from a plaster model, and when the work had been done he returned the model in a broken condition. The reason given by the plaintiff was that it was impossible to cast bronze from a plaster model without damaging the latter, as the damp sand used for making the mould had to be rammed with great force against the plaster and the damp injured it. The plaintiff said that this was especially the case where two bronze casts had to be made from the original model, and that in the present instance parts of the model fell to pieces after the second mould had been made. The plaintiff said that he had taken every precaution, and that he would not have undertaken the work if he had been expected to return the model uninjured. The plaintiff's witnesses stated that it would have been impossible to return the model in good condition after making two bronze castings. The defendant said that he had had considerable experience as a sculptor, and his models had never been returned in a damaged condition. In the ordinary course he would have expected that twelve casts could be made from one model. The defendant's witnesses said that if reasonable care had been taken the model would not have been damaged as it was. The jury found a verdict for £60 on the claim, and £8 on the counterclaim.

Buried Cities.

A REMARKABLE series of explorations has been carried out on the site of the ancient city of Susa (Western Persia), the Sushan of the Scriptures and the capital of the Elamite kingdom. The excavations of M. Jacques de Morgan in the great citadel mound at Susa, which rises about 105ft. above the plain, have unearthed the remains of no fewer than five successive cities or settlements one above the other, dating far back beyond the historic age into the neolithic period. The latest historical city is found at a depth of about 21ft. below the surface. Here were found brick buildings, but no trace of metals or writings, while 30ft. below this we find the earliest settlement, with rude pottery and flint implements. It is therefore clear that we have here evidence of a vast antiquity. In the lower strata of the mound large quantities of pottery were discovered, but all below the historical strata was hand-made, the use of the wheel, as in pre-dynastic Egypt, being unknown. The importance of these discoveries cannot be too highly estimated, as they undoubtedly shift the birthplace of civilisation from the alluvial plains of the Tigris-Euphrates valley further eastward.

A Queer Storey.

IN the Model Answers to Examination Questions published in our issue for January 24th, our contributors in quoting two of the questions inserted the word "(sic)" after the words "ground-floor storey" and "basement storey" (see page 385). We allowed the word to stand, thinking our contributors were questioning the correctness of the use of these terms, whereas they were actually pointing out the inaccuracy, as they considered it, of the spelling of the word "storey," which was thus written, though the "e" was inserted by our printers in accordance with the usual spelling adopted by us. The sequel is curious. We receive a letter from Mr. Ebenezer Gregg, who set the question at the R.I.B.A. Exam., pointing out that he spelt the word "storey," and expressing some indignation that he should be suspected of spelling the word with an "e." Almost by the same post we receive a letter from Messrs. Middleton and Carden, who are scarcely less perturbed at the idea that they should question the accuracy of the form "storey." Each of our correspondents is evidently quite sure that his form of spelling is the only correct one; the fact is, of course, that both are correct. Good authorities quote alternative forms. As to the use of the terms "ground storey" and "base storey," there is evidently some difference of opinion, but the matter seems to us to be of very little general interest.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Altering Windows: Rights of Light.

GREAT YARMOUTH.—H. writes:—"In a long workshop I have a number of small windows (ancient lights) looking out upon a neighbour's roof. Shall I be able to put in a larger window without incurring any liability for damages and without any sacrifice of present right, provided I do not carry the line of light lower than at present? Referring to the accompanying sketch (not reproduced), can I take out the brickwork between the existing windows and put in frames covering the whole?"

"H." can take out the brickwork between the existing windows and put in frames in the manner proposed, so as to enlarge the openings through which light enters his premises, without either incurring any liability for damages or any sacrifice of present right.

Handwriting for Civil Service Exam.

DUBLIN.—A SUBSCRIBER writes:—"I am thinking of sitting at the coming examination for Assistant Surveyors R.E.C.S., War Office, and I am informed that only the civil service style of handwriting will qualify a candidate for such a post. Is this so?"

There are no regulations as to any special style of handwriting for these examinations. It may be safely assumed that a certain number of marks are given for neatly written papers. Answers to questions have, as a rule, to be written on plain paper without lines. Full particulars of these examinations can be obtained, free of charge, on application to the Secretary, Civil Service Commission, London, S.W. HENRY ADAMS.

Questions in Heraldry.

PERPLEXED writes:—"I am very much interested in Mr. Cadogan Rothery's articles on heraldry and should like to have answers to several questions. My father married 'a woman who represents the last of her family,' and consequently has her arms in a shield of pretence. (1) Must my arms consist of my paternal and maternal arms quartered? If so, in which quarters do they go? Or (2), can I simply take on my paternal arms? (3) When a husband bears his wife's arms accolée to his own, do his descendants carry on their maternal arms in any way, or simply their paternal arms? (4) Are mine what are called 'Arms of Alliance'?"

(1 and 2) In strict accordance with the laws of heraldry, "Perplexed" should quarter the maternal and paternal arms. Custom, however, sanctions the omission of this formality when the paternal family is ancient or more distinguished than the maternal. In that case the quartered arms would be merely used on genealogical trees, &c. The paternal arms always take precedence—that is to say, they occupy the first, and are repeated in the last quarters. The first quarter is the dexter chief, but remember that "the dexter and sinister sides are so called from the position of the shield when worn against the chest of the bearer," consequently the herald's right is what an ordinary mortal would imagine to be the left. (3) No. A husband wears his wife's arms accolée merely to show his alliance, to assert his proprietary rights; just as a bishop impales the arms of his See to show that he intends to enjoy the fruits thereof. (4) Yes, they are arms of alliance. G. C. R.

Designing Roof Truss.

HASTINGS.—E. D. B. writes:—"I have a drawing of an iron roof truss to prepare for my R.I.B.A. final examination, with the strains on the several members worked out and their sizes stated. Would a reciprocal diagram be sufficient for this, and would you give a wind pressure diagram or take the wind pressure as equal to so much per superficial foot? Also, what book would you recommend me on the subject?"

In designing a roof truss, calculating the stresses, and determining the sections of members, a reciprocal diagram should be employed. The stresses are scaled from the reciprocal diagram and should be figured on the frame diagram. A wind pressure diagram would be desirable, as being more in accordance with the actual forces to be allowed for, and also as showing a more thorough acquaintance with the subject. The method of procedure is described in detail in "The Practical Designing of Structural Ironwork," Spon, 8s. 6d.

Lindfield Church, Sussex.

NEWCASTLE-ON-TYNE.—A PROBATIONER writes:—"I have prepared drawings of one bay of the main pier arcade (Perpendicular) of Lindfield Church, Sussex. Upon endeavouring to write a description of it, as required by the R.I.B.A., I find it exceedingly difficult to obtain any information. Can you kindly supply me through your columns with the necessary particulars? Could you also tell me in what book I can get a plan of St. Eustache, Paris."

It would probably be best for "Probationer" to send a stamped and addressed envelope to the Vicar of Lindfield Church, as information is difficult to obtain from any other source. In the "Sussex Archaeological Collections," Vol. II., there are some notes upon an ancient mural painting there, and in a later volume there is a passing reference to its having, or having had, or having been intended to have had (this not being made clear by the context) a parvise over the porch. Guide books content themselves by remarking that the church is "perp." A plan of St. Eustache will be found in "Eglise Saint Eustache, à Paris," by Victor Calliat. R. W. C.

Setting-Out Buildings.

BRISTOL.—E. W. writes:—"Please say how to set-out a building on the site, how to set-out square and level for foundations, &c. At what period of the work should the drains be laid?"

Where the site to be levelled is of tolerably small area, and variations of level do not exceed 10ft., pickets may be driven and levelled over the site with the aid of straight edge and mason's level. After the site is levelled the main front of the building should be determined by a line of pickets and the angles of the building accurately set off with building square checked with chain. The width of excavations for foundations may now be marked off. The method of setting-out a right angle with chain is to mark off four links on base line, three links perpendicular, and a tie line or hypotenuse of five links. Any multiple of three, four, and five may be used for greater accuracy. Drains should be laid before building operations are commenced, i.e., during the progress of excavations for foundations and levelling. HENRY ADAMS.

R.I.B.A. Examinations.

BIRMINGHAM.—PROBATIONER writes:—"What is the best book to use for subject 6 in the R.I.B.A. intermediate examination, Descriptive Geometry, the Projection of Solids? I should also be glad to know if Gill's Geometry embraces the whole of this subject."

Gill's Geometry is an excellent work on the subject, but for the R.I.B.A. intermediate it should be supplemented by Angel's "Practical Plane and Solid Geometry," price 1s. 6d. R. W. C.

DUDLEY.—SPHINX writes:—"Having passed the following examinations, I shall be glad to

know if they exempt me from the preliminary R.I.B.A. examination:—Oxford Junior, third-class College of Preceptors, and the following South Kensington examinations:—First-class Elementary Freehand, first-class Elementary Model Drawing, first-class Elementary Perspective, first-class Elementary Building Construction, first-class Advanced Model Drawing, second-class Elementary Shading, second-class Elementary Geometry, Sub. I, second-class Advanced Shading, second-class Advanced Freehand.

No. It is just possible that exemption might be obtained in geometrical and free-hand drawing, but to ensure even this, specimen drawings should be submitted in addition to the certificates. G. A. T. M.

Owen Jones Studentship.

DUNFERMLINE.—STUDENT writes:—"What are the requirements for the Owen Jones Studentship, as I wish to go in for it?"

Candidates for this Studentship must submit testimonials, with drawings exhibiting their acquaintance with colour decoration and with the leading subjects dealt with in Owen Jones's "Grammar of Ornament." Particulars of all the prizes offered are given in the R.I.B.A. Kalendar, which can be obtained for half-a-crown (postage about 4d. extra) from the Institute's offices at 9, Conduit Street, Regent Street, W.

Valuing Leasehold Property.

YOUNG VALUER writes:—"I have to make a valuation of several properties, all of which are leasehold; one lease expires in about fifty years. What is the difference to allow for between this and the others with 800 years' lease? Would it be a fair thing to reckon for the 800 years' lease to pay 6 per cent., and for the 50 years' lease to pay 7 per cent? The property is all house property (cottages) and not too well built."

In the valuation of leasehold properties for terms of years certain, the method is to allow for the setting apart of a certain sum, called a sinking fund, which will accumulate at the end of the term to the amount of the purchase money. Thus, in valuing a leasehold house for a term of fifty years unexpired, the real value is the full value obtained by multiplying the net income by the number of years purchase, taking the latter as perpetual, less a sum which will accumulate in fifty years to the amount of the purchase money. This may be worked out by compound interest, but the usual method, in order to avoid long calculations, is to refer to Inwood's Valuation Tables. These give the number of years purchase by which the annual value of the property is to be multiplied, to find its real value direct, with such sum deducted as would, if invested at the same (Table I.) or a different (Table VIII.) rate of interest, accumulate at the end of the term to the sum paid. Thus, the only difference between the value of a long and a short term is the larger sum which in the latter must be set apart as a sinking fund. To make this clear take your own example:—

First, the value of a leasehold house, term fifty years. From gross rent make all deductions, such as repairs, rates, ground rent, &c., leaving net annual income. £

Years purchase, at 7 per cent for fifty years' term (Inwood) . . . = 13.801

Full value allowing for sinking fund £

Second, in the case of a lease for a term of 800 years, such an income may for all practical purposes be considered as perpetual; therefore the purchase value is found by multiplying by the number of years purchase at the same rate of interest, taking the term as perpetual, in this case = $100 \div 7$ per cent. = 14.286 years. Provision must be made, however, in the case of a long lease, for the probable rebuilding of the whole property, which might come under the head of repairs. I would advise "Young Valuer" to get a copy of Inwood's Valuation Tables.

E. BRAND, P.A.S.I., &c.

THE DESIGNING OF ELECTRICAL GENERATING STATIONS.*

By A. ROBERTS, M.S.A.

THE first matter to be considered in connection with the designing of electrical generating stations, and one which naturally largely affects the design, is the selection of the site. In doing this many matters of vital importance to the ultimate economical working have to be considered. It should, if practicable, be near a river, canal, or railway, so that coal may be unloaded direct from the barges or trucks into the coal bunkers, obviating the necessity of cartage, which involves a large extra outlay each year. It should not, if possible, be in the centre of a residential neighbourhood, as this involves many difficulties, such as complaints as to alleged vibration, noise, smoke, condensed steam, &c., in most cases unfounded, but at the same time involving cost to refute. One instance in this respect came under my notice where adjoining owners brought an action for damages in respect of vibration. They stated they had kept careful note of the times when the vibration complained of was extremely bad, and the worst period was when the company in question was able to prove that no engines were running. Another instance was a chimney shaft in the centre of a residential neighbourhood in connection with a generating station, which had been disused for this purpose on account of the company requiring much larger works, the chimney shaft, therefore, being entirely out of use, and having no flues or boilers connected with it; notwithstanding this, complaints were made by adjoining owners of the smoke, &c., but in this case, happily, it was not difficult to refute the alleged nuisance.

Another consideration in selecting a site is possible actions for damage to ancient lights. Care, of course, is necessary in all cases, but more particularly so in the case of an electric light company, most persons thinking that a company of this description with a large capital behind it is "fair game to shoot at," and, therefore, endeavour to obtain injunctions and other pleasant legal hindrances which are annoying to the architect, who is generally pressed to rush up the building as quickly as possible.

One other, and although last, by no means least important thing to be considered in selecting a site is space for future extension. In starting, a company does not usually wish to overburden itself with a large capital and therefore the ground taken is often only sufficient for the building immediately required; in the course of a few years, as the company grows and has to meet a larger demand for supply of current, more generating plant is required and further building becomes necessary, and this then means either having two or more stations with a larger staff required than is concentrated in one station only, or in obtaining statutory powers (in itself an expensive luxury) and the compulsory purchasing of the various interests of adjoining owners and occupiers, when enormous claims have to be met and compensations paid. It is therefore false economy in the first place not to acquire a large enough site for all contingencies of extension and growth which may be anticipated for many years to come. Other matters in selecting a site have to be considered, such as the nature of subsoil, facilities for drainage into parish sewers, &c.; but as these are common to all building operations, and not special to electric light buildings, I will make no particular reference to them.

Having considered the questions relating to the acquisition of the site, the next matter for consideration is the design and construction of the buildings. In the first place, it is usual for an electrical engineer to decide upon the system of supply to be adopted, and to formulate a scheme and prepare sketch plans showing disposition and space required for

machinery, plant, &c. The architect then has to design his buildings to meet the requirements of the engineer, and practically as a shell to cover and protect the engineering plant. The ideas and wishes of the electrical engineer should therefore always be studied and adopted, as the primary function of a building of this description is the supply of current, and not as a testimony of the architect's artistic taste (if he has any). Engineers' architectural ideas, however, as a rule do not run on parallel lines with those of an architect (for instance, Vauxhall Bridge), but the *suaviter in modo* system is far more preferable than endeavouring to force one's own taste and inclinations. The plan of necessity depends to a large extent upon the shape of the site, but simplicity and economy of working should be the key-note. It is needless to say that in the London district the buildings must be planned in accordance with the Factory Act and also the London Building Act, the latter, however, has special clauses relating to electrical generating stations, by which the Council has power to authorise buildings to be erected of greater cubical dimensions than 250,000 cubic feet, and in other respects to exempt such buildings from any of the provisions of the Act if they think fit.

The following are the principal departments for which provision must be made in the plan: (1) Coal stores; (2) boiler house; (3) engine house; (4) workshops; (5) stores; (6) meter and testing rooms; (7) engineers' apartments; (8) offices and also battery rooms, if any batteries are proposed to be erected at the generating station.

(1) *Coal Stores*.—These should be situated adjoining and readily accessible from the boiler house. They should be divided into a number of bunkers to obviate danger of fire and for other reasons; one to each pair of boilers is a convenient arrangement, so that a check may be kept upon the consumption per boiler. Generally, however, on account of contingencies of site the coal bunkers cannot all be placed near the boilers, in which case it is necessary to have a system of iron tip-up trucks running on narrow gauge rails from the vaults, with turntables at any point where the trucks have to turn at right angles. The doors to bunkers should be of iron, hung to lift with counter-balance weights; the flooring is usually of concrete or blue Staffordshire bricks. Where the coal is shot into bunkers out of carts, it is well to have several removable coal plates and shoots to each bunker, rather than one central one, as in the latter case it is difficult to fill the coal bunker to its utmost capacity without trimming the coal, which entails much labour. As to the capacity of coal vaults, sufficient coal should be accommodated to supply the boilers for at least three weeks or a month, and, of course, if space is available, the greater amount of coal storage capacity the better.

(2) *The Boiler House*.—A convenient arrangement, where practicable, is for the boiler house to run parallel with the coal bunkers, and also with the engine house. It is usual to sink the level of the boiler house floor some 8ft. or 10ft. below that of the engine house, so that the steam pipe from the crown of the boilers may be conveniently placed with regard to the engines, and so that coals may be shot down from the ground level into the coal bunkers beneath, the flooring of which being necessarily at the same level as the boiler-house floor for ease of stoking. The space required in the boiler house depends upon the type and size of boilers, but there should be a space of at least 16ft. to 18ft. between the boiler and the wall opposite the fire door, for convenience of stoking and so that boilers, drums, and tubes may be conveniently removed, swung round, and replaced with new ones; and for this purpose also large doors must be provided for ingress and egress of new and old boilers, as may be required in the course of years.

The boiler house should be lofty, well lighted and ventilated by a continuous skylight running from end to end of the building, with louvre boarding at the sides, the skylight being glazed with one of the many patent systems of glazing, rather than by the old-fashioned wooden bars. Space must be pro-

vided in the boiler house for further engineering plant, in addition to the boilers, such as feed-water heating and detartarising apparatus, Green's economisers, &c., depending upon the scheme adopted, and particulars of space required for these must be obtained from the engineer when planning the building. Stokers' lavatory and urinals should be provided readily accessible from the boiler house, and a stokers' mess-room with cooking range, &c.

With regard to the chimney shaft or shafts, if a single shaft is decided upon, it is best to place it in the centre of the range of boilers, with the horizontal flue running right and left, so that boilers may be added as the works grow, and in selecting the position of the shaft future extension must be borne in mind. It is however advisable, where funds and space permit, to have two shafts of smaller capacity rather than one shaft of large capacity, so that in the event of repairs being necessitated through damage from lightning or other causes one may be shut down whilst the other is working. The area of the shaft should also be amply large enough to provide for all future boilers that may be required, and in the London districts particularly it is advisable to carry up the shafts at least 150ft. to 200ft., so as to distribute the products of combustion at as high a level as possible. The shaft must also, of course, be designed in the London districts in accordance with the regulations of the Building Act. I fear it would be wearying and extend this paper too much to touch upon the calculations requisite in designing a shaft relating to draught, wind pressure, stability, &c., all of which, however, are of much interest; but I must content myself now by making a few general remarks relating to construction only. There is a diversity of opinion as to the best form of chimney, some authorities arguing that a circular chimney is better than a square one; but the shape usually adopted for electrical stations is an octagonal form of unequal sides, or, rather, a square chimney with the corners taken off. In calculating the area, it must be remembered that the actual effective area of a chimney is less than the entire internal superficial area of the shaft, as the velocity of the gases is retarded by friction on the sides of the shaft, and it is usual to take for the effective area the total area less 2in. all round.

The horizontal flue conveying the gases from the boilers to the shaft should be of a larger sectional area than the shaft, as these get constricted by deposit of soot, and if entering the shaft from opposite sides a midriff or central division wall should be carried up the centre of the shaft some 15ft. or 20ft., constructed of firebrick. The shaft foundations of necessity are of vital importance, and must be of sufficient area to carry the load, which is usually very great, without sinking into the ground beneath. They should be allowed to stand some months before the brickwork of the superstructure is commenced, as it takes some time for a large body of concrete, 30ft. or 40ft. square by 8ft. or 10ft. deep, to set. The bricks should be specially selected, particularly at the base, to withstand the load, which often amounts to eight tons or ten tons or more per foot super; they must not, with the exception of the cap and footings, be laid in cement, on account of its unyielding nature, and its inability to stand heat so well as lime mortar; besides a shaft built in cement usually cracks. The materials should be frequently tested during the erection of the shaft, particularly bricks for crushing strains.

An extremely good mortar for shafts which I have used, and which is used largely in the North, is composed of blue lias lime, sharp sand, and foundry ashes, in the proportion of one of lime, two of sand, and three of ashes; the joints should be kept thin, and to prevent the shaft being blown out of the upright before the mortar has set the brickwork should not be carried up too quickly. A special bond is often adopted for shafts, in which a large number of stretchers is used, as longitudinal tenacity is required to prevent a shaft splitting; for this reason hoop-iron bond, well tarred and sanded, should also be built in at frequent intervals. In selecting the position

* A paper read on Saturday 25th before the Society of Architects.

for a shaft, it is preferable that it should stand alone, and not be attached to any buildings. If, however, from necessity of plan it must be in continuation of the walls of a building, there should be no bond between the shaft and the wall adjoining, but a straight joint to allow the shaft to expand and contract; also, it should be built first, so that any settlement may take place before walls are built adjoining.

The cap should be of simple design, not of too great projection, and little or no stonework employed in its construction, as in the event of this becoming disintegrated by frost it is costly and difficult to repair, and a heavy cap causes the shaft to oscillate in a wind with longer pulsations, and there is more chance of its being overthrown. A cast-iron capping, built up in sections and bolted together, forms, to my mind, the best finish at the top, and to this the lightning conductor may be readily fixed and stayed. The shaft should be frequently plumbed to ensure a uniform batter, and great care should be taken in its construction to see that no bats are used.

A firebrick lining is necessary, which should be carried up according to the height of the shaft some 80ft. to 100ft., the firebricks being laid in fireclay and usually carried up perpendicularly (i.e., with no batter), with a space averaging about 2in. between the outer wall and the lining. It must have no bond with the outer wall, and to steady it headers with sand joints are usually projected through the 2in. space at intervals to touch the lining. To prevent soot and cinders falling and blocking up the 2in. cavity, the brickwork of the shaft must be racked out to cover up the cavity at the top, but room must be left to allow the firebrick lining to expand. It is essential in firing a chimney for the first time that heat should not be applied too suddenly, or there is danger of the chimney splitting, so it is well to allow a little heat to pass up for some weeks before it is necessary to use it to its full capacity.

Foot irons are usually built into the interior of the shaft from base to cap to afford access for repairs, &c., and in most electric generating shafts the exhaust-steam pipe is carried up the centre of the shaft, and the stays to keep it upright must not be bonded into the firebrick lining or main walls, but should rest on the offsets where the brickwork is reduced in thickness, to allow the exhaust pipe to expand and contract; as this exhaust pipe and the heated column of steam inside forms the readiest path for a flash of lightning, it must be carefully earthed and connected up to the lightning conductor. The boilers usually adopted in London stations are of the water tube type, as with these steam may be more quickly raised than with any other form, and this is an essential where sudden fogs and consequent darkness are so prevalent.

(3) *The Engine House.*—This, as I before said, should be parallel if possible with the boiler house so that steam pipes from boilers are as short as possible and may be carried direct through the separating wall to the engines; its dimensions, of course, depend upon the number of engines and type proposed, and here the engineer must again be consulted. It must provide accommodation not only for the engines and dynamos, but for switch boards, and should also either contain engineers' mess-room and lavatory, or have these conveniently adjoining. It should be lofty, well lighted and ventilated by either skylights or ranges of windows so planned that through ventilation may be obtained, as it is essential not only for the personal comfort of the staff, but also for the plant, that the temperature should not be too high. Cleanliness is of extreme importance in the engine house, as dry gritty particles in the atmosphere, or blowing about in the wind, would shortly do irreparable damage to the bearings of the machinery, revolving at such high speeds as its does. For this reason, therefore, it is usual to face the walls (and, where stores and other departments are over the engine house, the ceiling also) with glazed bricks, which are cleanly and reflect the light, ensuring a bright engine house. These may also be easily wiped down, so saving the annual cost of distemping or painting the

wall surfaces that would otherwise be necessary.

Window frames in the engine and boiler houses should be of steel or iron, rather than of wood, as the unavoidable high temperature causes the latter to shrink and wind, and the former are also more fireproof. An overhead traveller is essential in an engine house for the erection and removal of engines, dynamos, &c., and corbels should be built in the walls as the works proceed, or some provisions made for carrying the rails upon which it travels. The flooring of the engine house must receive careful consideration. It should be carried entirely independently of the engine beds, so that the vibration set up by the engines may not be transmitted; and it should be paved with some cleanly, insulating material, if possible, non-slipping. Wood-block flooring soon gets greasy and unsightly, and the best material I have found so far is unglazed red tiling, although this has the objection of not being a good insulating material.

The engine beds are usually constructed of a continuous block of concrete (not separate beds for each engine), which is carried down 6ft. or 8ft., and carefully constructed and planned so that vibration shall not be transmitted to the ground beneath. Many methods have been tried, successfully and otherwise, to prevent the transmission of vibration, and that adopted at the Chelsea Station, which has proved very satisfactory, is to first construct a foundation of concrete 9in. deep, on this sheet lead is placed, then two layers of continuous matting similar to an ordinary door mat, but very much thicker, on this lead sheeting is again laid, and on these insulating layers the concrete superstructure of the engine bed, about 7ft. deep, is erected.

The position of the holding-down bolts for the engines must be ascertained, boxes constructed and accurately placed in the right position before the concrete is shot into the beds, so that after the concrete has set, the wooden boxes may be taken out and the holding-down bolts, with anchor plates attached at the bottom, may be let into the cavities thus formed, and grouted in with fine concrete and cement.

Switch boards should be constructed of some fireproof material, slate slabs in timber framing being one of the best forms of construction. The switch boards should be raised one step above the engine-house floor level, on a continuous platform, so as to isolate the switches and enable the operator working them to have a good view of the engines and dynamos. India-rubber mats are provided to stand on when operating the switches. A convenient office should be arranged, if practicable, for the electrical engineer in charge, with a window looking into and commanding the working of the engine house.

(4) *Workshops* must be provided for carpenters, engineers, and fitters, &c., with lavatories, mess-room, and office for foreman, the floor space for these depending upon the size of the works; there is little in their construction of special interest.

(5) *Stores.* These are an essential department of an electrical station. They should be conveniently situated near the workshops; also, if on the upper floors, lifts and hoists must be provided in connection with them. Racks are requisite for the various articles stored, and an office at the entrance for the storekeeper. The stores generally, like the whole of the building, should be of fireproof construction, and a special store provided, with iron doors, for oil. In calculating the strains and stresses in steel construction carrying floors of stores, it is well to err on the side of excess, as the loads carried are usually very great.

(6) *Meter and testing rooms* have nothing special to call for remark; stoves should be provided here for warming purposes, and benches for storing meters, for testing, &c.

(7) *Engineers' apartments* should be situated naturally with the best outlook, and, if over the engine house, made sound, as well as fireproof, as far as possible. The accommodation required of course depends on the number of the staff.

(8) *Offices* are often situated away from the

generating station, and must provide accommodation for secretary and staff, chief engineer and staff, draughtsmen's rooms, and board rooms; they have nothing special that calls for note. Battery rooms must be well ventilated to allow gases to escape, and the floors should be of cement, or acid-proof asphalt, with channels to carry off contents of the cells if they should get broken. Accommodation must be provided on the roof, in some convenient and accessible position, for water tanks, as a large storage of water is essential, so that in the event of burst mains or other causes preventing supply, no inconvenience is occasioned.

With regard to construction generally, an electrical generating station should be substantial, and of fire-resisting materials, as it is of extreme importance to prevent fire, not only on account of the damage done to the works, but because a fire would damage plant and prevent the supply of current, which is a most serious matter. Also, the premiums charged by insurance companies for electrical buildings are extremely high in any case, and would be more so unless the building throughout were of a fireproof nature. A system of fire hydrants should be fitted throughout the building, and in most electrical stations the staff are exercised in fire drill. All walls (at any rate those of engine house) should be carried down to same level as the foundations of the engine beds, and a clear space should be left all round the building between external walls and those of adjoining buildings to prevent the transmission of any vibration.

There are many other points in the planning and construction of electrical generating stations that require consideration, but I hope to have given some general idea of the special matters to be thought of which may prove of interest.

Views and Reviews.

AN ELECTRICAL DIRECTORY.

The Universal Electrical Directory for 1900 is more bulky and comprehensive than ever before. It now comprises 26,397 names and addresses of members of the electrical and kindred industries throughout the world, and for simplicity and facility of reference it is divided into four groups—British, Continental, American, and Colonial—each of which is again divided into sub-sections. In addition to the new names incorporated in the present issue, much financial information is given, the telegraphic addresses and local telephone numbers are given, and the whole forms the largest and oldest electrical dictionary extant. The present is the nineteenth year of publication, which says much for the manner in which the book is appreciated by those whom it concerns.

"The Universal Electrical Directory (J. A. Berly's)." London: H. Alabaster, Gatehouse and Co., 4, Ludgate Hill, E.C. 7s. 6d.

A GEOMETRY PRIMER.

As set forth in the preface, this little book is intended for candidates reading geometrical drawing for the Science and Art Department, South Kensington, Elementary Stage, for entrance to Sandhurst and Woolwich, and for the Cambridge Preliminary and Junior Local examinations. The problems are clearly and concisely explained, and well illustrated, which is an important feature. The most interesting portion of the book is, however, that giving solutions to questions set in the Science and Art, Civil Service Commission, Cambridge Preliminary and Cambridge Junior Local examinations; these solutions should be of great help to the students for whom the book is primarily intended.

"Geometrical Drawing" (Part I: Plane and Elementary Solid). By W. H. Blythe, M.A. London: C. J. Clay and Sons, Cambridge University Press Warehouse, Ave Maria Lane, E.C. 2s. 6d.

A new Market at Brighton, to cost £10,000, is a proposal which has received the sanction of the Town Council.

Professional Practice.

Ipswich.—In March last building operations were commenced on a new parish hall in connection with St. Matthew's Church, Ipswich. A house and garden, with a frontage of 92ft. to Clarkson Street, were purchased, and the hall is now completed. Mr. H. J. Wright is the architect, and Mr. Robert Girling the builder. An entrance hall divides the large room from the two club rooms, but in addition there are lavatories for both parts of the building, and a well-equipped kitchen. White brick and stone have been used for the outside of the building. The hall, measuring 42ft. by 31ft., with a height of 14ft., is lighted by a five-light stained glass window, and from the roof by a large lantern. It has a wood-block flooring, and is heated by hot water, is well ventilated, and fitted with incandescent lights. A platform with canopied recess has been provided and on the background has been fixed a movable screen for lantern entertainments. At the rear of the hall there is a ladies' retiring hall with lavatories, under which the heating apparatus has been fixed by Messrs. Huff and Son, hot-water engineers, of Ipswich.

Keighley.—The new Queen's Theatre and Opera House, which has been designed by Mr. Frank Matcham, of London, was opened last Saturday. The area of the site is about 7,000 square feet and the building has a frontage of 86ft. to Queen Street and 48ft. to Adelaide Street. A glass and iron verandah has been erected over the pavement for the whole length of the front. Admittance to the best parts of the house is at the Lawkholve Lane side of the building. This entrance leads into an attractive vestibule, giving access to the pit stalls, and a wide and well-decorated staircase leads to the dress circle. The pit has tip-up seats of polished birch. At each end of the dress circle is placed a private box, so designed as to blend with and increase the attractiveness of the internal scheme of construction. The decoration is in the style of Italian Renaissance, the gallery fronts being of fibrous plaster, and in front of each of the private boxes is a panel bearing the name of Shakespeare in the one case and Sullivan in the other. Around the large sunlight in the centre of the roof are four paintings depicting the seasons of the year. The stage has been considerably increased in size, and the dressing rooms are quite separate from it. An installation of automatic sprinklers is furnished throughout, and a fireproof curtain of iron and asbestos has been provided. A row of sprinklers has been fixed immediately over this curtain, and should a fire occur the plugs in these will melt, and the result will be a constant stream of water flowing upon the back of the curtain. In the construction of the building every care has been taken, so far as possible, to make it fireproof, and not only about the stage, but in every part, stone and concrete have been most extensively used with this end in view. Heating is by radiators on the low-pressure system, and the electric light has been installed, supplemented by gas. The following have been the contractors for the various works:—Builders, Messrs. Greenhow and Murgatroyd, Keighley; fibrous plaster and decorations, Messrs. Dejong, London; electric installation, Messrs. Grace and Sutcliffe, Keighley; iron and glass shelter, Messrs. McFarland, Glasgow; upholstery, &c., Messrs. Dean and Co., Birmingham; carpets, &c., Messrs. Turner, Son and Walker, Liverpool; iron and asbestos curtain, Messrs. Oldroyd, Leeds; gasfitters, Messrs. Jenkins and Tollerton, Leeds; Grinnell sprinkler installation, Messrs. Dowson, Taylor and Co., Leeds; act-drop, Messrs. McCullough, Salford; general scenery, Messrs. Edgerton, Bradford; ropes, &c., Messrs. J. Sharp, Keighley. Sub-contractors:—Masonry, Messrs. Waddington Bros., Oxenhope; steel girders and pillars, Messrs. Foster Bros., Preston; hydrants and fire apparatus and heating apparatus, Messrs. Oldroyd, Leeds; general ironwork, Messrs. Hird, Shipley; plumbers, Messrs. J. Harrison, Keighley; plasterers, Messrs. Greenwood, Cross Hills; painters, Messrs. Lonsdale

and Sons, Keighley; stage and all machinery, Messrs. J. W. Cawdrey and Co., London; high-speed engine, Messrs. Crossley Bros., Manchester; dynamo, the Electrical Engineering Company, Morley. Mr. E. Swann, of Leeds, acted as clerk of works.

Leeds.—The new church at Chapel-Allerton, Leeds, which has been erected from designs by Mr. G. F. Bodley, A.R.A., at a cost of nearly £20,000, is in the Decorated style of the fourteenth century and consists of nave, with aisles, chancel, and chapel for daily service, situated on the south side of the chancel. The nave is separated from the aisles by lofty arcades of clustered columns and arches. There is no clerestory, but a high roof of panelled wood, painted and gilded in a style unusual in the North, but frequently found in old west country churches. One of the principal features of the interior is a carved oak screen separating the nave from the chancel and supporting a considerable part of the organ, which is enclosed in a handsome case, painted red and gilded. The remainder of the organ is situated in the north aisle. This division of the organ is usually found to produce an admirable musical effect; and, probably owing to the panelled roof, the whole building possesses a peculiar resonance which will beneficially affect the singing of the choir. The walls are of Ancaster stone, and the dressings of Bath stone. Some very handsome gifts have been made to the church. The late Mr. J. W. Naylor (who contributed £5,000 to the building fund) gave the organ; also the beautiful stained-glass east window, which is a memorial of his deceased wife. This window, which was designed by Mr. Bodley and executed by Messrs. Burlison and Grills, of London, has four lights, displaying the figures of St. Matthew St. Peter, St. Augustine and St. Aidan. The window at the east end of the side chapel is also of stained glass. The carved oak screen is the gift of Mrs. J. J. Cousins, in memory of her husband. The oak stalls for the clergy and choir have been presented by Miss Clark, and the sedilia will be the gift of Miss Firth. The brass lectern is given in memory of the late Mr. and Mrs. Charles Naylor by their son and daughter. It consists of an eagle, the work of Mr. H. J. M. Furze, mounted on a pedestal and a marble base designed by Mr. Bodley. Messrs. Stephens, Bastow and Co., Limited, of Bristol, were the contractors for the new church.

Mundford, Norfolk.—St. Leonard's Church, Mundford, has been restored by Messrs. J. Springfield and Son, builders, of Swanton Morley, under the direction of Mr. A. J. Lacey, architect and diocesan surveyor, Norwich. The nave has been refitted with a new oak roof with hammer-beams, and covered with Broseley tiles. It was found in removing the old principals that some were in an excellent state of preservation, and, where possible, these have been preserved and used again. At the east end of the chancel two new buttresses have been erected to each angle. On the south side of the nave a new buttress has been added of flint and Weldon stone dressings. The south-west window was found to be dilapidated and its tracery partly gone. This has been restored with Weldon stone. The churchyard being very much higher than the nave, it was decided that a dry area should be arranged around the entire building, and this has been laid out with Staffordshire blue bricks. The walls have been generally repaired with rubble bedded in cement. An entirely new vestry of flint, with Weldon stone dressings, has been erected on the north-east side of the chancel. The interior of the nave has been re-stuccoed throughout, and the hammer-beams and cornice have been ornamented by means of cusplings. The unsightly old gallery on the south-west side has been removed and the wall filled up. The old belfry has been removed and replaced by a new one of red battens. An Estey organ with two manuals has been placed in the chancel, whilst new heating apparatus has been supplied by Messrs. Reeve and Sons, of Norwich.

Keystones.

Sir Thomas Lipton's Cheap Restaurant is almost completed. The building is four storeys high and has a red granite portico facing City Road, at the corner of Baldwin Street.

Glasgow Exhibition Buildings.—The tender of Messrs. W. Shaw and Son for the grand concert hall and restaurant, amounting to £14,497 1s. 6d., has been accepted. The entire work is to be completed by January 31st, 1901.

York Architectural Society.—The report of this Society for the past two years has, as a frontispiece, a good half-tone illustration of York Minster, 1898. Mr. William Bell, F.R.I.B.A., is the president for the present session, and there are now fifty-four members on the roll.

A New Calendar has been sent us from the London Drawing and Tracing Office (manager, Mr. John B. Thorp), 98, Gray's Inn Road, W.C., a copy of which will be sent to any applicant. It is of a handy size, and, though the colour scheme is not all that could be desired, it forms a bright and cheery spot on the wall.

Housing Problem.—A public conference upon the housing of the people in town and country has been organised by the Fabian Society, and will be held in the Memorial Hall, London, on March 1st next. This conference is to be held in conjunction with the Trade Union Conference on Labour Representation, which is to assemble in the same building on the last two days of the present month.

A New Font at Holy Trinity Church, Dorchester, has been made by Messrs. Harry Hems and Sons, of Exeter, and is now being placed in position. The bowl and base are of English alabaster, and there is a middle column of Castellino marble surrounded by four others of alabaster. The railings are of hammered iron and polished brass, and were made by Messrs. W. and R. Feacey, of Dorchester.

Pulling Down Chimneys.—A brick chimney 16ft. high and 8ft. square at the base, and 4ft. in diameter at the top, has been overthrown in St. Louis by the use of hydraulic jacks. The chimney was first undermined on one side, and three 10-ton hydraulic jacks were placed in position under the side. A hawser was then fastened about the chimney, 60ft. from the ground, and ropes led from this hawser to crabs placed at a distance of about 100ft. from the chimney. With eight men at each crab and men at the hydraulic jacks, the chimney was slightly lifted and pulled at the same time; the men at the jacks left their posts at the first warning crack, but those at the crabs continued their work until the chimney fell.

London County Council.—At the meeting of the Council held on Tuesday in last week, recommendations were passed authorising the erection of a new fire station at Shepherd's Bush (cost, £13,230) and a new School of Economics and Political Science on the Council's land in Clare Market. A motion instructing the Housing Committee to proceed forthwith with the erection of dwellings on the Churchway (Somers Town) area was carried. The Main Drainage Committee recommended that the Council should invite tenders for the construction of an additional northern outfall sewer, estimated to cost £600,000. Mr. Cornwall thought the manager of the Works Department should be asked to report as to the price he could do the work for. He consequently moved to refer the report back. This amendment was carried. The influence of the war was seen by some names which the Building Act Committee was asked to pass for new streets at Muswell Hill (a part of Central Finsbury). Three streets are to be called Methuen Park, Colesburg Park, and Rensburg Park; two other new streets in Woolwich are to be called Enslin Road and Ladysmith Road; two streets in Hoxton are to be incorporated under the name "Redvers Street."

A New Organ at All Hallows' Church, Leeds, has been built by Messrs. Abbott and Smith, of Leeds.

A New Organ at the Royal Academy of Music has been built by Messrs. Henry Willis and Sons. It takes the place of the instrument set up in 1876.

A New Peal of Ten Bells at St. Mary's, Beverley, has been provided at a cost of about £1,500. Messrs. Taylor and Co., of Loughborough, were the founders.

Another Cromwell Statue.—A bronze statue of Oliver Cromwell, 7ft. 6in. high, is to be erected at St. Ives, Hunts. Mr. F. W. Pomeroy has been given the commission. The cost will be about £1,300.

The new Town Hall and Municipal Offices at Chatham is in the English Renaissance style. The main feature is a square and high corner tower, surmounted by a domed belfry with clock faces. The facings are of Monkspark stone, which is light in colour. £30,000 has been the cost of the building.

Was Stonehenge a Sun-Dial?—An immense sun-dial was once upon a time formed by the thirty stones of Stonehenge, suggests Dr. Alfred Eddowes. The stones, with their intervals, divided the circle into sixty equal parts, the grooved stone being used for supporting a pole which formed the pointer of a sundial for daily observation, or an indicator of the time of year by the length of the shadow.

New Town Hall for Batley.—A Local Government Board inquiry was held at Batley on February 1st into the application of the Town Council to borrow £36,000 for the erection and furnishing of the new town hall and the extension of the open market. The Mayor and Town Clerk emphasised the inadequacy of the present structure, which was built for a Mechanics' Institute, and purchased in 1874 by the Corporation at a cost of £4,900.

South Kensington Art Council.—The Lord President has appointed Sir William Richmond, K.C.B., R.A., Mr. T. G. Jackson, R.A., Mr. E. Onslow Ford, R.A., and Mr. Walter Crane as a Council to advise the Department of Science and Art on art matters relating to Art Schools and Classes, the Art Museum, and the Royal College of Art. He has also appointed Mr. A. Spencer, Headmaster of the Municipal School of Art, Leicester, to be Headmaster of the Royal College of Art.

Colchester's New Town Hall.—Mr. W. Gurney Benham, of Colchester, sends us a copy of the second edition of the illustrated pamphlet dealing with the new town hall and municipal buildings that are in course of erection from designs by Mr. John Belcher, A.R.A. Messrs. Kerridge and Shaw, of Cambridge, secured the contract for £33,397, and are to complete the work by Michaelmas next. The pamphlet, which has been enlarged, contains a list of gifts promised, required, and suggested.

A Proposed Ruskin Union.—Mr. Frederic Harrison will preside at a meeting to be held at the St. Martin's Town Hall on Thursday February 8th, the eighty-first anniversary of the birth of John Ruskin, when the Rev. J. B. Booth, M.A., of St. James's, will deliver an address on "The Life and Work of John Ruskin," in which suggestions will be made for the formation of a Ruskin Union for the study of Ruskin's works. Admission will be by tickets, which may be had on application to Mr. Mark H. Judge, 7, Pall Mall, S.W.

New Board School at Paisley: Result of Competition.—At a meeting last week of the Paisley Burgh School Board the minutes were that Mr. Watson, architect, and Mr. Mathieson, measurer, had submitted their reports on the competitive plans lodged for the new school at Renfrew Road. The architect reported that, in point of convenience of arrangement, he was of opinion that the design under the motto of "Economy" occupied the first place. The measurer's report showed that the probable cost of the building in accordance with that plan would be £18,843, or £13 8s. 3d. per scholar. A protracted discussion took place, when it was ultimately agreed not to accept any of the plans lodged.

New Patents.

These patents are open to opposition until March 10th.

1899.—Continuous Muffle Furnaces.—1,805. W. DICKEN, Hanley, W. WADE, Longport, and L. L. GRIMWADE, Stoke-on-Trent. The object of this invention is to prevent cracking or "dunting" of pottery or other ware during firing. The kiln is circular and has an entirely closed muffle, the fire-hole being at the opposite side of the kiln to that in which is the opening (the only one) through which goods are passed or taken out. Within the muffle is a circular table mounted on wheels and capable of being revolved from the outside by means of rack and pinion. The iron or clay boxes containing the articles to be fired are placed on this table, which is then turned, the firing being thus controlled and adjusted.

Roofing Tiles.—2,798. J. J. HAMMOND, Rhyl. The tile is preferably made of cement or concrete, and of the usual size (10in. by 7in.). It is quite flat on the underside and has an ogee moulding along each side edge, so formed that when two tiles are placed together the ogee joint overlaps and the top face is level. About 1½in. from the upper edge of the tile a cross-bar is moulded, and a panel is formed by sinking the middle portion. When in position, the flat back on one tile rests on the cross-bar of the tile below, and they all fit very compactly together. Only thirty-six are required to cover one square yard, as compared with seventy-eight ordinary tiles. The overlap is about 3in.

Wall Coverings.—3,109. W. RUTTENBERG and M. VAN ZANTEN; both of Dordrecht, Holland. A series of frames are fastened to the wall and are covered with sheet metal plates, previously ornamented with a drawing or pattern by lithographic means. The sheets are bent round the edges of the frames.

Girders, Beams, Trusses, &c.—3,930. A. WESTWOOD, Tipton. This invention is to allow girders, beams, &c., to expand and contract with more freedom without undue strain on their abutments. It consists of three parts:—(1) A bearing plate having a semi-circular trough supported by ribs; (2) an intermediate crescent-shaped bearing block, with a hollow on its upper side; and (3) a top plate having a transverse swelling fitting in this hollow.

Cement Burning.—4,252. P. RUNGE, Yospommern, Germany. To prevent the cement caking to the sides, the kiln has fitted round it, in its hottest portion, a water jacket. When burning is considered complete, the water supply is increased so that it overflows into the furnace uniformly, quenching the cement and preventing it caking to the walls.

Tool Handles.—7,696. J. H. WEBB, Cardiff. As applied to planes, the invention consists of a top and bottom bracket and a wooden handle fitting between. The brackets are fixed to the plane body with screws, and the upper side of the bottom one is recessed to receive the end of the handle, which is fixed by a screw passing through it from the top bracket to the lower one.

Fireproofing Solutions.—22,085. A. J. BOULT, London (A. Nieske, Dresden). To render them fireproof, fabrics or documents are impregnated with a 10 per cent. solution of molybdate of sodium. This chemical does not injure the articles treated like metallic salts.

The following specifications were published on Saturday last, and are open to opposition until March 17th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1898.—21,688, BAKER AND BAKER, refuse destructors.

1899.—245, WILLIAMS AND WALFORD, radiator for hospitals, infirmaries, &c. 470, COOPER AND COOPER, continuous kiln. 941, BROWN, apparatus for the automatic delivery

and discharge of sewage and other liquids to and from filter beds. 1,139, FIEGLMUELLER, closing cap for use in impregnating timber, beams, piles, &c. 1641, TULLOCH, apparatus for use in the purification of sewage and other polluted waters. 2,699, BARRATT, acetylene lamps. 3,145, LOMAX and TOMLINSON, door knobs and latches. 3,303, CLARKE, faucets for flushing tanks. 3,332, TATTERSALL, tubular heaters for steam or fuel or hot water as a medium to heat air. 3,342, SMITH, waste pipes, overflow pipes, &c. 3,552, MILLS (*Soc. Anon. des Fontaines à Gaz*), gas burners for heating purposes. 3,653, EDWARDS, brick moulding and pressing machinery. 4,066, LEWIS, construction of slate mantelpieces. 4,418, DYMOND (*Lönnbeck*), ventilating and heating apparatus. 5,177, ADAMSON, cutter for dressing slates, tiles, &c. 5,201, SCOTT, screw-down taps and cocks. 5,295, ALDAM, HEATON AND CO., LTD., and CROFT-SMITH, construction or manufacture of sash bars for domes, skylights, windows, &c. 5,307, SOUTHERN AND SPILSBURY, device for adjusting the cutting irons or blades of planes, spoke-shaves, &c. 5,450, *Soc. Anon. des Usines du Pied-Selle*, heating apparatus. 7,065, ROGERS, ladder and tape connections for Venetian blinds. 9,036, CAREY, improvements in windows to facilitate cleaning them. 11,149, BOGAARD, nut lock. [Date applied for under International Convention, October 29th, 1898.] 18,156, CARLAND, hinged casement opening and closing mechanism. 19,469, FRANK, method of forming pipe joints. 19,628, WATROUS, water-closet valves. 20,469, WINDLE and MEARES, attachment of corrugated iron sheets to roof purlins. 22,084, HUGHES, taps, tap holes, &c. 22,155, CHICK, means for fixing woodwork to walls. 22,451, ENGELKE and MEYER, valve for the delivery of hot and cold water. 23,157, BUTCHER, fire extinguishing apparatus. 23,458, MÜNCH-PHIPPS, fireproof ceilings. 23,616, MCKINNON, windows. 23,871 BURROWS, locks and latches. 23,936, BURROWS, manufacture of door knobs. 23,953, PHILLIPS (*McDougall*), fastenings for door handles. 23,963, LAKE (*Peck, Bros. and Co.*), taps or faucets for wash-basins, &c. 23,981, THOMPSON (*Westfälische Metall-Ornamenten-Fabrik Rob. Osv. Leutert and Co.*), lattice windows. 23,982, CHARLES, glue-applying machines.

New Companies.

Mineral Plaster and Cement Co., Ltd.

This company was registered on January 23rd, by Shaw and Sons, Fetter Lane, E.C., with a capital of £500 in 5s. shares, to adopt an agreement with G. Ollier, and to carry on in the City of Nottingham or elsewhere the business of plaster and cement manufacturers, &c.

Walker and Crawshaw, Limited.

This company was registered on January 18th by Jordan and Sons, Limited, 120, Chancery Lane, W.C., with a capital of £35,000 in £1 shares, to acquire the business carried on by Walker and Crawshaw, at Conisbrough, Yorks, and to carry on the business of brick, tile, pottery, and earthenware manufacturers and merchants, quarry owners, timber merchants, sawmill proprietors, &c. The first directors (to number not less than four nor more than five) are G. Walker (chairman), G. Crawshaw, L. T. Crawshaw and R. Crawshaw. Qualification, £500. Registered office: The Works, Conisbrough, near Rotherham.

General Tramways Construction Syndicate, Limited.

This company was registered on January 16th by Goldberg and Co., 2 and 3, West Street, E.C., with a capital of £200,000 in £1 shares, to enter into any contract for the construction of rail and tram roads, the subject of the concessions bearing date December 22nd, 1898, and July, 1899, granted by the Federal Assembly of the Swiss Government Republic to Francois Forestier, for the construction of rail and tram roads in the Canton of Geneva, and, generally, to carry on the con-

struction, execution, carrying out, equipment, improvement, working, development, administering and controlling of public works of every description. The first directors are L. Hirsch and L. Neumann.

Atmospheric Steam Heating Co., Limited.

This company was registered on January 18th by Ashwell and Co., 79, Queen Street, E.C., with a capital of £10,000 in £1 shares, to adopt an agreement between Ashwell and Nesbit, Limited, and J. Simpson and Co., Limited, of the one part and A. E. Hawkesley (for the company) of the other part, and to carry on the business of heating, ventilating and mechanical engineers, iron-founders, metal workers, &c. The first directors (to number not less than two nor more than seven) are B. Simpson, of London, and A. T. Ashwell, of Nottingham. Registered office: 55-6, Chancery Lane, W.C.

A. Kellett and Sons, Limited.

This company was registered January 19th by C. Doubble, 14, Serjeant's Inn, E.C., with a capital of £70,000 in £1 shares, to

acquire by purchase or otherwise, as a going concern, the business of builders and contractors as now and hitherto carried on under the style or firm of Abram Kellett at the Old Oak Wharf, Willesden, Middlesex; and to develop and extend the said business. The first directors (of whom there shall be not less than two nor more than five) are the first three signatories to the memorandum of association. Qualification, £500. Remuneration not specified.

Lloyd's Avenue Estate Company, Ltd.

This company was registered on January 17th by Turner and Co., 101, Leadenhall Street, E.C., with a capital of £100,000 in £5 shares, to adopt and carry into effect a certain agreement for the acquisition of certain lands, buildings and hereditaments of any tenure in the county of London, and to develop, deal with, and turn to account the same in such manner as the company shall see fit. The first directors (of whom there shall be not less than three nor more than five) are J. Dixon, E. H. Watts and a third to be elected by the signatories. Qualification, £1,000. Remuneration, £100 per annum each.

The North British Granite and Whinstone Quarries, Limited.

This company has been registered in Scotland with a capital of £20,000 in £1 shares (5,000 six per cent. preference, and after ordinary shares have received eight per cent., to rank for a further two per cent.), to carry out agreements with the Kilsyth Whinstone Quarries, Limited, and John Freebairn, quarrymaster, Kilsyth, and to carry on the business of quarrymasters, brickmakers, merchants, &c. Registered office: 44, Renfield Street, Glasgow.

Lumley Brick Company, Limited.

This company was registered on January 26th by King and Co., 11, Queen Victoria Street, E.C., with a capital of £20,000 in £50 shares, to acquire the business of the Lumley Brick Company, Lumley, Durham, and to carry on the general business of brick, tile, terracotta, and earthenware manufacturers, quarrymasters, &c. The directors are R. Herron, G. A. Atkinson, W. R. Waddingham, J. Lunn, and W. Dodd. Qualification, £500. Remuneration to be fixed by the company.

CONTRACTS OPEN.**BOROUGH of SHOREDITCH.**
ERECTION OF CHIMNEY SHAFT.
CONTRACT No. 22.

The Shoreditch Vestry invite TENDERS for the ERECTION of a CHIMNEY-SHAFT about 180ft. high of brickwork, on the site of their new Electric Generating Station, situated in Whiston-street, adjoining Haggerston Basin.

The specifications, quantities, and forms of Tender can be obtained, and drawings can be seen, at the Office of the Engineers, Messrs. KINCAID, WALLER, and MANVILLE, 29, Great George-street, Westminster, on payment of a fee of Three Guineas, which sum will be returned on receipt of a bona-fide Tender.

The Vestry do not bind themselves to accept the lowest or any Tender, and the contractor whose Tender is accepted shall enter into a formal agreement under seal with sufficient sureties for the due fulfilment of his Contract.

Trade Union rates of wages and hours to be observed. Sealed Tenders, endorsed "Tender for Chimney Shaft (Contract No. 22)," to be sent at or before NOON on TUESDAY, FEBRUARY 13th, 1900, to

H. MANSFIELD ROBINSON,
Town Hall, Vestry Clerk and Solicitor.
Old-street, E.C.

COMPETITIONS.**PARISH of LEICESTER.**
TO ARCHITECTS.
COMPETITION FOR NEW INFIRMARY AND PAVILIONS FOR IMBECILES.

The Guardians of the poor of the parish of Leicester invite architects to submit COMPETITIVE DRAWINGS for the ERECTION of the proposed NEW INFIRMARY and other buildings at North Evington, Leicester.

Premiums of £100, £50, and £25 are offered for selected plans, and in the event of the author of a selected design being employed to carry out the work the premium awarded will merge in his commission.

A copy of the conditions and plan of site may be obtained on application to me, and designs must be addressed to, and deposited with, me at the "Poor Law Offices," 3, Pocklington's Walk, Leicester, before TWELVE o'clock on SATURDAY, APRIL 28th, 1900.

BOROUGH of RAWTENSTALL.
OPEN COMPETITION FOR LAYING OUT PARK AND PLAYGROUND.
TO ARCHITECTS, LANDSCAPE GARDENERS, AND OTHERS.

The Committee appointed for the purpose of LAYING OUT and EQUIPPING the proposed Park and Playground at Oak Hill, Rawtenstall, invite Architects Landscape Gardeners, and others to send in COMPETITIVE PLANS, &c., for Laying Out and Equipping the same, and offer the following Premiums for Plans adjudged of sufficient merit and passed First, Second, and Third in order respectively, namely: First Premium, £50; Second Premium, £30; Third Premium, £20.

The premiated drawings will become the absolute property of the Committee, and the successful competitor may be selected to carry out the work, in which case the premium will merge in the commission.

The Committee will be assisted with professional advice when adjudicating on the plans.

Copy of conditions and Plan of site may be obtained on application to Mr. A. W. LAWSON, A.M.Inst.C.E., Borough Surveyor, Municipal Offices, Rawtenstall, on payment of £2, which will be returned on receipt of Competitive Plans, &c.

Plans, &c., must be delivered as directed in the conditions at the Municipal Offices, Rawtenstall, on or before FRIDAY, MARCH 30th, 1900.

By order,
JAMES WHALLEY,
Town Clerk.

FIG. 2.—ELEVATION OF A DERRICK TOWER GANTRY.

CONSTRUCTING A DERRICK TOWER GANTRY.*

By G. ELLIS, A.B.I.C.C.

THE derrick tower is now much used in extensive building operations; the practically unlimited height to which it can be built, and the great command over the whole site which it affords, make it a favourite appliance of the up-to-date builder. In addition to its mobility, it is, in reality, an economical contrivance, as, with the aid of the derricking power of the crane, a stone, or girder, or other material may be deposited at any desired spot on the site. It thus allows a much lighter scaffolding to be employed in building the walls than would otherwise be possible, and after the first cost of construction little expense will be incurred, as its striking and re-erection may be entrusted to unskilled labourers under competent supervision.

The erection is usually built up on the site of the interior of the building, in such a position as not to interfere with any important structural arrangement. It may consist of one, three, or four-framed piers or towers; the one shown in the accompanying illustrations is a three-tower derrick. These towers are each square on plan and arranged in the form of an equilateral triangle; they are connected at the top by trussed girders carrying a plat-

form of deals, that support the derricking crane and provide a landing stage for its loads. Each tower has sides about 6ft. wide, and is composed of four corner posts, either solid

balk or built up of three 9in. by 3in. deals, resting on a plank foundation and braced both horizontally and diagonally on each side; the horizontal struts are arranged in bays about 10ft. high, and the diagonal ones cut between them.

The tower which supports the crane is provided with a central standard to further strengthen it, the other two having stout chains brought down through them from the feet of the crane stays to ring bolts in the foundation planking; the object of doing this is to prevent the overturning of the crane. The bottom portions of each tower are filled in with bricks, stone, or sand to counteract the effect of the loaded crane. The weight in each should be equal to twice the maximum load to be lifted. As the crane can only make a three-quarter revolution in consequence of the back stays of the mast intervening, no load can be deposited immediately behind it; therefore, it is not usual to truss the rear girder connecting the two anchor towers. The other two, as before mentioned, are trussed both to stiffen the towers and to enable them to carry the load on the platform.

The trussed girders may be made from 5ft. to 8ft. deep, according to the size of the tower. The top member or head, generally of 11in. by 4in. red deal, runs diagonally across the heads of the towers and projects over the front about 4ft. by 5ft. to carry the landing stage. The timbers are halved together where they intersect each other over the head of the standard. The sills rest upon the horizontal braces of the towers and are bolted to the corner posts; the two members are tied together by several $\frac{1}{2}$ in. iron screw-rods, and are kept apart by struts placed at the sides of the rods, thus dividing the truss into bays about 6ft. wide. These bays are each braced diagonally by counter struts, as the strains change their direction according to the position of the crane jib when in use.

Fig. 1 shows the plan of a three-tower gantry, one half showing the construction of the parts immediately below the stage or floor, and the other half the arrangement of the stage above. Fig. 2 is an elevation parallel with one of the trusses. Figs. 3 and 4 are enlarged details of the bracing of the tower.

The usual method of procedure in building a gantry of this kind is to form each side of a tower separately on the ground, first building up the corner posts to the required length and, as shown in Fig. 3, bolting them together with $\frac{1}{2}$ in. by 10in. screw bolts. The nuts should be kept outside for convenience of striking, and those in positions to be covered by the bracing should be sunk in flush as shown. The longer deals forming the posts should also be kept on the outside as there will thus be less joints to bolt. Bolts need only be put in near the joints. The position of the horizontal braces are set out by laying off the points with a 10ft.

FIG. 1.—PLAN OF A DERRICK TOWER GANTRY.

DUTIES OF A FOREMAN MASON.

By JOSHUA PAUL.

A MEETING of the Masons' College took place last Tuesday week at the Royal Architectural Museum, Tufton Street, Westminster, Mr. G. Goodley in the chair, when Mr. Joshua Paul gave a lecture on "The Duties of a Foreman of Masons." The meetings of this institution are characterised by their thoroughly practical character, and Mr. Paul's lecture took the form of a series of hints to junior masons upon the methods to be adopted to fit them for the position of a foreman. Mr. Paul said that after having been shown over the department of the employer whose services the foreman was entering, he would then be left to himself, and it would be as well to start by enquiring about the system of booking in and out of all raw or worked stone, &c. Having obtained such information, if a more simple system could be seen, or any improvement could be made, it should be at once suggested; but at all events, the foreman should always arrange so that he had a copy of such booking himself. This copy would be found most useful in case of disputes, such as in the case of clerical errors in the office. If the sawing were done by hand, the booking was usually done by the foreman. As the sawyers were, in the lecturer's opinion, a very troublesome class of men, always grumbling, for instance, when sawing bath stone, that the stone was hard, or else wasting time, perhaps, in getting the block from the stack, it was, in his opinion, necessary to make oneself acquainted with the prices of sawing different stones. More especially would this become necessary if the foreman was required to prepare an estimate, this being in many cases part of his duty. If the sawing was done by steam machinery, it was also necessary to have a system for the booking of the cuts. A good system was to have a board, or a book in preference, ruled out and given to the sawyer, which the foreman should insist on being kept correctly. By this means the foreman would be able to find the prime cost of the sawing, as well as the sizes. Where the cutting was for the trade, this system would be most useful if there was a dispute when the account was sent in, for all machinery was always charged to the foreman's prime cost in preparing the stonework.

When the drawings and details were given for a job, the date and time of receiving them should be always made a note of. The foreman should take great care in working out his details to the general information given on the plan and elevation, and also to that given in the specification, where it was possible to obtain a copy. In some firms a list of the quantities was given, and in this case it would be a duty to call the attention of the front office to the discrepancy, in case it required more stone to finish the job than was given in the quantities. It was usual for the heights of floors and window openings to be given

be as well to visit the job and consult the general foreman with reference to some of the questions, which in many cases only he could settle. Also a truthful diary would be found a most valuable book, especially if the stonework should be under a sub-contract. Having got the queries settled, the foreman should then prepare his own working drawings to a suitable scale. Mr. Paul preferred to use a 1 in. or 1 1/2 in. scale. A copy should also be traced for the fixer, to whom the foreman should give all the information he could consistent with simplicity; for instance, the drawings should not be overcrowded in any way that was likely to cause confusion to him. A most particular point should be made of giving figured dimensions.

The lecturer preferred to give each stone a number. Some foremen added a letter to a number. He agreed that it would be as well to add a letter if the work was on a building lotted off in blocks; or where circumstances required this to be done, as on a return, or where it had been originally arranged to make out a space in one stone, and it was afterwards found that the same could also be done with two stones with the advantage of perhaps forwarding the job.

Having prepared so much of the working drawings, the sawyer could be started. First the sizes should be taken off on a board, and numbered if saw frames were used. The sawyer should be given a copy of these, and he would look out the block nearest to the sizes of the stones wanted. If Bath stone was being cut by hand it were well to check the block and make a sketch of it, and by referring to the list the cuts could then be marked out and the sawyer immediately started. By making a sketch of the block and making the saw cuts on it, it also gave a check for the stock in hand. In addition to being able to start the sawyer, the foreman would be in possession of the sizes of his cuts. It might be thought that this system was introducing a lot of writing or that it was complicated, but once everything was prepared plenty of time would be found to be in the presence of the men, and any question that might be asked could be answered easily.

Having proceeded so far the setting-out and mould cutting could be proceeded with, unless there were a mould-cutter. If there were a mould-cutter he would work from the foreman's working drawing. Even then it were well to run through the moulds and check them by taking off the sizes and numbers, and mark the mould with the proper information for the mason. The conditions should be described as plainly and as fully as possible, so as to avoid too much labour being spent. Thus joints, whether stone or brick, or how far the return was seen, and so on, should all be stated, because a lot of unnecessary labour was sometimes spent, and this would all count against the foreman mason's prime cost or cost of labour, which he was responsible for.

The following is a specimen tabular statement of particulars made by Mr. Paul in sawing various stones:—

No. 1 FRAME.

Number of Block.	Stone.	Item.	Time of Starting.	Date Started.	Time Finished.	Date Finished.	Number of Cuts.	Size.	Super.
4872	Portland (Hard)	789	9 a.m.	Aug. 23	8 a.m.	Aug. 26	4	4' 5" x 3' 6"	61' 10"
1694	York	2210	9 a.m.	Aug. 26	3 p.m.	Sept. 6	4	8' 6" x 4' 0"	136' 0"
324	Red Mans.	2116	10 a.m.	Nov. 19	2 p.m.	Nov. 23	1	6' 6" x 4' 0"	26' 0"
533	field						1	7' 8" x 4' 4"	33' 2"
4536	Spinkwell	1427	11.30a.m.	April 17	9 a.m.	April 18	5	4' 3" x 1' 3"	26' 6 3/4"

on the section, but, if these particulars were omitted, they should be ascertained at the earliest moment, because these items also affected the foreman carpenter and foreman bricklayer. In going through the drawings the foreman should provide himself with a strip of paper (a pocket-book preferably) on which to note all questions or queries separately. These queries should then be settled as soon as possible; sometimes it would

In reply to several questions asked him, Mr. Paul stated that he had found sawing by machinery paid if the machine were kept going, but not otherwise. An iron mason would work about four times as fast as hand labour. A large stone was rubbed quicker than a small one, by reason of it allowing of more weight being put upon it, for if the man rubbing it put much weight on a small stone it would break. He had found

FIG. 4.

FIG. 3.

FIG. 3.—CONSTRUCTION OF CORNER POSTS.

FIG. 4.—JOINT IN DIAGONAL BRACES.

rod, starting at the bottom end of each post. The braces are then cut off to length—the two opposing sets 6 in. longer than the two adjacent sets, to enable them to run over the ends of the latter—and are then fixed in position with coach screws. The frame is next "squared" and the diagonal bracing cut in and bolted. All the pieces are correspondingly marked with a chisel, the braces then taken off, and the other sides made up in a similar manner.

When all the sides have been thus prepared and marked, the corner posts are separated into convenient lengths for handling and are raised upright on the platforms, previously levelled and bedded to receive them. The positions of the platforms are determined by the size of the crane used; that is, the distance of the feet of the back stays or length of the sleepers from the mast. The posts are temporarily braced with boards until the first series of transoms are bolted on, when they will stand of their own accord. After this the diagonal bracing is put in place, completing the first bay, and upon the top planks are laid to form a scaffold for the men to work upon in raising the next bay—and so on until the top is reached. The standard to support the crane must be arranged in position as soon as the first bay of the mast tower is erected. The beam connecting the two anchor towers is next fitted and fixed, and a temporary platform thrown across from the other tower for the men to stand on whilst hauling up the trussed girders. These latter are framed together on the ground, all the posts and braces being stub tenoned into the heads and sills. They are dropped into position as shown on the plan and bolted to the corner posts. A cross beam is fixed on the ends of the girder heads by means of tusk tenons, and four main joists are trimmed into it and taken right through to the rear beam. These carry the landing stage in front of the crane; they are half-notched where they cross the trusses. Other smaller joists are framed into the girder heads where required to carry the rear staging. This is usually composed of 3 in. by 9 in. deals, about every sixth one being spiked down. A 3 in. by 3 in. handrail 2 ft. 10 in. high, running all round the stage and framed into uprights which are bolted to the trusses, &c., will complete the structure.

that a surface was planed more cheaply in a machine, using a Hunter's "Duplex," than by being rubbed by hand. By Hunter's machine, plain work could be done for about 3d. per foot super; the machine could also be used very advantageously on round work. Mr. Paul considered chilled steel shot could be used for sawing by hand, and was preferable to sand by reason of it cutting cleaner. The shot should never be exposed to the air, or it would become rusted into a mass. Lime water was best for preventing it from rusting. The only fault about shot was that, owing to it being so fine, it was apt to get mixed with any sand there might be about, and thus, if several kinds of stone were being sawn, scour the face of the softer stone, especially in the case of marble.

Mr. G. Goodley, the chairman, in thanking the lecturer, said, he (the speaker) appreciated the system put before them that night, more especially as it was one very similar to that used by himself. He had found that in from five to ten minutes you could find what any man had done to-day, yesterday, or even months ago. The booking system was the best and the fairest one. A man who was ten hours longer over a job would generally be found to have done that amount of work, and by this system of booking allowance could be made. Also, if there were a clerical error in the office, by this system you could usually point out where the error had arisen.—Mr. Paul briefly replied, and the meeting terminated.

Engineering Notes.

A New Reservoir at Kingskerswell. Newton Abbot, has been built at a cost of about £2,034. The reservoir's capacity is 62,343 gallons and water is supplied by the Torquay Corporation from their trunk mains by meter. Mr. Rogers was the engineer for the work.

Belgian Electrical Enterprise.—A Belgian company has just concluded with the Corporation of Tsaritsin, on the Volga, a very important contract for (1) the electric lighting of that town; (2) an electric tramway; and (3) an electric railway for the transport of timber from the river to the different saw-mills in the town. The contract is for thirty-five years and under conditions very favourable to the company.

The Barrage of the Nile.—Mr. John Aird states that great progress is being made with the Nile dams. At Assouan the Bab-el-Kebir, Bab-el-Sogair, and Bab-el-Haroun channels have been closed, and the works at these important points are being vigorously proceeded with. Two-thirds of the main wall will be practically completed this season, and the masonry of the navigation channel has been commenced. At Assiout the works are so advanced that it is hoped this dam will be completed a year earlier than the contract time. About 15,000 men are now employed.

Leeds Gas Supply.—Owing to the large increase in the consumption of gas in Leeds, the Gas Committee are considering the question of erecting additional works. In that event it is more than probable that a carburetted water-gas plant will be put down. The general manager (Mr. Townsley) estimates that the cost of such a plant capable of making two and a half million cubic feet of gas per day would be about £30,000. The water gas so produced could be mixed with the ordinary coal gas. This is being very successfully done in London, Liverpool, Birmingham, Manchester, Belfast, and Edinburgh. Mr. Townsley does not anticipate that there would be any material saving in the cost of production, as compared with ordinary coal gas, but its great advantage is that the plant can be got to work much more readily than the coal-gas plant. The ordinary retorts require four or five days' stoking before they are any use, whereas a water-gas plant can be in full working order in less than a day. In a changeable climate like ours, with sunshine one day and fog the next, the benefit of this readier means of regulating the supply will be easily appreciated.

Masters and Men.

The Paris Exhibition Carpenters' Strike came to an end last Tuesday week.

The Strike of Plasterers at Scarborough has come to an end, and the men returned to work last Monday.

Strike at Rauceby.—The bricklayers employed by Messrs. Kirk, Knight and Co., in the construction of the new Kesteven County Asylum at Rauceby, near Sleaford, have struck work for an increase in wages from 9½d. to 10d. per hour.

The National Association of Master Builders of Great Britain and Ireland held their forty-fourth half-yearly general meeting last Tuesday week at St. Martin's Town Hall, London, Alderman W. Houldsworth, of Bradford, presiding. The proceedings were conducted in private. After the consideration of various trade subjects, Mr. W. Sapcote, of Birmingham, was elected chairman for the ensuing year.

The Association of Master Painters in Scotland held its annual meeting at Edinburgh last Friday, when the following officers for the ensuing session were elected: Councillor W. Fraser Dobie, of Edinburgh, president; Mr. Alexander Latto, of Aberdeen, vice-president; and Mr. W. B. Crawford, of Glasgow, re-elected secretary and treasurer. It was decided to hold the next annual meeting at Aberdeen.

Dundee Joinery Trade.—Several alterations in the by-laws for the current year have been suggested by the employers. The chief of these are in connection with the wages question. According to the by-laws at present in force, the masters are bound to pay the standard rate of wages to all the men in their employment, and they now suggest that an alteration shall be made whereby the full rate should be paid only to competent men. Another alteration they propose is that the clause giving an hour's grinding time—an hour to sharpen tools—should be abolished. The suggestions have been laid before a special meeting of the operatives, who resolved to resist any effort to alter the by-laws in the way proposed. Something akin to a deadlock has thus been reached. No notice to reduce the wages by 1d. per hour has yet been made to the operatives.

The Bristol Master Builders' Association held their annual meeting last Thursday, under the presidency of Mr. F. N. Cowlin. Mr. George Humphreys was elected president for the ensuing year and Mr. G. M. Gosling vice-president. Mr. G. Humphreys was re-elected treasurer, and Messrs. E. Walters, E. J. Neale, J. Lovell, G. Wilkins, F. N. Cowlin, F. A. R. Woodward, G. L. Poole and A. Dowling were elected members of the committee, together with the president, vice-president and honorary vice-presidents. The report of the committee, which was confirmed, stated that notices had been received from the federated building trades demanding an increase of wages at the expiration of six months and other alterations in the working rules. The masons and bricklayers' societies had also given notice for an advance of 3d. per hour. These matters would have to receive the early attention of the association. Respecting the long-debated subject of depositing priced bills of quantities with the employer upon the signing of the contract, this question had been brought by the Association under the notice of the Society of Architects, and the hon. secretary replied to the effect that as priced bills of quantities were, in the opinion of the members of his society, confidential documents, they considered that the same should be entrusted to the architect alone, holding, as he did under the contract, the position of a disinterested arbitrator between the parties, and that this was the universal custom with private clients and was even more desirable with regard to public bodies.

Builders' Notes.

Enclosing Building Hoists.—In an action heard in the Court of Session for Scotland a mason's labourer named Thomas Roche sued Messrs. Hutchinson and Grant, of Glasgow, for £100 as damages for personal injuries received through a hoist descending on him. He averred that the well of the hoist, which was used for lifting building materials, was not barricaded. This the defendants denied. Verdict for the defendants.

The Defects in the Workmen's Compensation Act were recently summed up by Mr. C. H. Green, in a paper read before the members of the Insurance Institute of Yorkshire, as follows:—(1) Absolute failure to provide for the unavoidable accidents arising in the course of employment; (2) lack of precision as to the employments included; (3) indefiniteness as to the scale of compensation to be awarded; (4) no security that the workman will receive the compensation to which he is entitled. Compulsory notification of all accidents, on systematic lines, by the employer, and supplementary returns by the insurance companies were suggested as a remedy for the fourth defect.

Scaffolding: Another Decision.—In the case of *Maud v. Brook*, heard recently in the Court of Appeal, claim was made by a widow in respect of the loss of her husband, who, when the accident occurred, was at work on two villas which were being built by the defendant at Victoria Park, Leeds. Judge Greenhow had awarded the applicant £296. The master appealed, and two questions were raised for decision—namely, what was the meaning of the words, "a building being constructed," and "scaffolding," as used in section 7 of the Act. That section enacted that the statute should apply only to employments by the undertaker as thereinafter defined, and one of these employments was "on, in, or about any building which exceeds 30ft. in height, and is either being constructed or repaired by means of a scaffolding." Mr. Ruegg (for the master) said there was no question as to the houses being more than 30ft. high. The deceased man was a plasterer and he was working on the top floor of one of the villas finishing off the wall of the landing with a "float." The houses had been roofed, and the scaffolding was still up outside, although the outside work was practically finished. The banisters had not been put up, and the evidence showed that the plasterers used boards, supported by trestles, to reach the ceilings and the upper portions of the walls. Maud's mate saw him last "floating" the wall of the landing on the top floor, and he was then not standing on any ladder or other erection. Soon after that the sound of a fall was heard, and, hurrying up, his fellow workmen found that Maud had, in some way, overbalanced himself or stepped backwards over the landing, and fallen down on the floor below. He was conveyed to the hospital, where he died from concussion of the brain. The County Court Judge found that the accident happened to Maud whilst engaged on a building more than 30ft. high, which was being constructed by means of scaffolding. Appellant said that finding was wrong, first, because plastering a house was not a work of "construction"; and, secondly, that Maud was not at work—could not have been at work—on scaffolding 30ft. high when he met with the accident, which had nothing whatever to do with the scaffolding at all.—Lord Justice A. L. Smith: "The section of the Act does not say the scaffolding must be 30ft. high."—Mr. Ruegg: "That is true; but the scaffolding must be of the kind that is popularly known by that name—upright poles, with spars or boards lashed to them, upon which other boards are placed, to enable men to work at a height above the ground. I say that boards placed on two trestles, or on two chairs or boxes, is not such a kind of scaffolding as the Act here refers to."—Lord Justice A. L. Smith: "What is a scaffold must be a question of fact in each case. We held that a painter who was repainting an old house by means of a ladder and a board reaching from a rung of the ladder

to the window was not at work on a scaffold."—Lord Justice Collins: "If a board on two trestles or on two chairs is a scaffold, where would you draw the line? Suppose a workman was repairing a ceiling on such a scaffold, and another workman tumbled up or tumbled down the stairs, and broke his leg, would the master be liable? He met with the accident while at work in, on, or about a building being erected or repaired by means of a scaffold."—Mr. Ruegg replied, if the word was not limited to a high scaffold of the kind commonly known by that term, the decisions of the Court must be carried *ad absurdum*. He submitted that the word scaffold in the Act did not cover the boards and trestles used by plasterers when finishing out an ordinary room. The defence pleaded was that the employment of Maud at the time of the accident was not an employment to which the Act applied, and he pressed the Lords Justices to allow the appeal.—Mr. Crompton, for the workman, contended that the decision of the learned County Court judge was right. There was nothing in the Act defining or limiting the kind of scaffold by means of which the building was being erected, and, therefore, a board on trestles was a scaffold. A house was still in course of erection till the walls were plastered and the banisters put up.—By a majority the appeal was dismissed, with costs.

Annual Cement Trade Report.—The year just closed has been a record one for the cement trade. In all large producing countries—the United Kingdom, Germany, Belgium, France, and the United States—supply has barely kept pace with demand. In this country, whilst the trade has had a prosperous year, the margin of profit has been reduced, owing to increased expense of production, caused by higher cost of fuel and labour. The outlook for the year on which we have just entered is bright. Stocks are not heavy, and the building trade continues healthy. Large public works will probably absorb considerable quantities of cement during the next twelve months. Exports are as follows:—1898, 325,674 tons; 1899, 353,615 tons. Whilst exports to the United States, as compared with 1898, show a reduction of 10,000 tons, the consumption in other markets has been well sustained, notably in South Africa, South America, and Canada. We quote current prices as follows:—First-class brands, 6s. 3d. to 6s. 9d. per barrel f.o.b. export str.; good merchantable brands, 6s. to 6s. 3d. per barrel f.o.b. export str. Whilst, undoubtedly, the tendency in prosperous times is to increase production, we are of opinion that the English mills during the present year have attained their maximum output for the present, although in an article like cement an increase is more quickly effected than in many other staple manufactures. One feature worthy of record in the United Kingdom trade is the increasing consumption of foreign cements in this country. Whilst accurate returns are difficult to obtain, we estimate imports into the United Kingdom for 1899 to be not less than 120,000 tons. The bulk has consisted of Belgian natural cements, which, when of reliable manufacture, can be safely employed on all ordinary building work. With regard to Germany, taking the trade as a whole, there is more disposition to meet consumers on individual orders, but for contracts ahead the mills have not so far made any material reduction off last year's prices. Throughout the year the mills of Belgium have enjoyed a good trade, inland consumption being fairly large. The artificial cement works claim to have made a record year, not only as regards the turnover, but also in price. The natural cement mills also have been favoured with an exceptionally active demand both for home and export consumption. In conclusion, the cement trade starts the year well from a statistical point of view, and we believe that the present estimated production for 1900 will not more than suffice for the trade in view. At the same time periods of prosperity like the present tend to over-production, and in time, undoubtedly, supply will overlap demand. The foregoing information has been supplied us by Messrs. Tulloch and Co., importers and exporters of cement, 4, Fenchurch Avenue, London, E.C.

Trade and Craft.

TIMBER AND BRICK DRYING.

In the matter of catalogues the American Blower Company, heating and drying engineers and contractors, of 70, Gracechurch Street, London, E.C., do not do things by halves, for they publish particulars of their goods in various languages—English, French, Norwegian, Swedish, &c. They send us catalogues numbered 115, 117, and 119. By the first of these (in English) we see that in the A.B.C. automatic dry kilns the timber is placed on trucks having steel roller-bearings, and enters at one end, is dried, and comes out at the other end, no handling being required. The air circulation is quite automatic, and is produced and controlled solely by its absorption of moisture, so that the more moisture there is in the wood the stronger becomes the circulation. The wood meets the dampest air at the commencement. The kiln is not costly to erect, and one 120ft. by 20ft. will dry about 20,000ft. (say ten standards) of pine boards daily. Exhaust steam is always used when available, but the cost of live steam is low as there are no condensers, cooling surfaces, fans, or chimneys, and no heat is wasted. Catalogue 117 deals with the A.B.C. fan system of heating and ventilation, while catalogue 119 (in French) gives particulars of the A.B.C. system as applied to brick, tile, cement, starch, soap, and other works. It may be mentioned that the firm's American works are at Detroit and its English works at Bedford; while there are branches at Amsterdam, Brussels, Drammen, Gothenburg, Hamburg, Lille, Moscow, Odessa, Paris, and St. Petersburg.

"THE IDEAL FITTER."

This is the title of the illustrated catalogue, price list and reference-book of the American Radiator Company, of 143, Queen Victoria Street, London, E.C. At first glance one might suppose it an American conception, for it is extremely neat, clear and handy, a feature which we see in most American goods. It is a peculiar fact, rather an unpleasant one perhaps for us, that we rarely seem able to make such clever, compact things as our American cousins; the English oil-can, for instance, is a bulky arrangement, soldered; while the American article has its edges turned up, or the solder is used so cleverly as to be scarcely visible. In the catalogue now under review there are some very pleasing radiators illustrated, both for water and steam, ornamental or plain. The "Colonial Wall Radiator" is built up of sections, one or more of which can be taken out without interfering with the rest in the stack. They are thus very handy. Of special radiators, there is one with a gap in it for fitting round the window, and another, in which the pipes diminish in height, to fit at the side of the staircase. Numerous boilers are shown in the catalogue; besides which there are many valves, cocks and fittings and tools used in connection with heating. At the end some useful data and tables and some "Hints for Fitters" are given. There is also a telegraph code for ordering goods. The company inform us that they will be happy to send a copy of their catalogue free to anyone interested in the heating trade.

NATURAL VENTILATION.

As in many small matters each man has his own particular system, so with the great question of ventilation "there are many Richmonds in the field;" and all this despite the innumerable efforts that have been made on every hand. There is not the slightest doubt that, where possible, nothing can equal "natural" ventilation in its truest sense—that is, say, by throwing open windows and doors and letting the fresh-air current sweep through and carry away the impurities. But this is often impossible, either on account of draught or cold. You have then to employ one of two systems for supplying fresh air and extracting the foul—the natural or the artificial system. The essential difference is that the one requires mechanical means and

appliances and the other does not, and the one that does not—the natural system—has in this respect a great advantage over the other. When the decision has been made as to which system to adopt there still remains the most important question of the position of the air inlets and outlets. It should be remembered that respired air is raised in temperature to 98.4 F., which is nearly that of the blood, besides which it has lost a fourth of its oxygen and received in substitution carbonic acid and putrescible matter. The coal we burn in our grates gives off three times its own weight of carbonic acid, in addition to sulphurous acid, and other gases, and every gas burner using about 3ft. of gas per hour vitiate the air to the same extent as three men. All these things have to be remembered when considering a system of ventilation. The products of respiration and combustion, becoming hotter than the surrounding atmosphere, naturally rise to the ceiling or roof. If you employ a natural system of ventilation, this impure air is drawn off by the extractors and a corresponding amount of fresh air is let in (by the Boyle system) at the floor level; so that the persons in the room or building breathe fresh air all the time. When the inlets are above and the outlets below, the conditions are reversed, and the vitiated air collected near the ceiling or roof is drawn down and re-breathed, which is naturally most undesirable.

The name of Mr. Robert Boyle is a very familiar one to everybody connected with the ventilation of buildings. It is now fifty years since Mr. Boyle, senior, in conjunction with Professor Faraday, first devoted himself to this subject, and his successor, the present Mr. Robert Boyle, has carried on the work with wonderful energy and success, visiting all parts of the globe to inspect the various methods in operation. The new illustrated catalogue which has been sent us by Messrs. Robert Boyle and Son, Ltd., of 64, Holborn Viaduct, London, E.C., and of Glasgow, is the most handsome of its kind that we have seen. It is a good size, and besides being well printed and illustrated on good paper, is enclosed between stout cloth covers. To quote their own words, it is published "not only as a business catalogue, but also as a practical treatise on ventilation and how it may be successfully achieved with the simplest means by an intelligent comprehension of the laws which govern the movements of air and the utilisation of the powerful natural forces which are unceasingly in operation." The Boyle system consists of a patent self-acting "air-pump" ventilator, combined with improved air inlets, the essential head or source of power being in this case produced by the difference in temperature of the inside and outside air. The catalogue is replete with authorities praising the system, and has at the end a supplement with coloured diagrams, illustrating the action of natural and mechanical methods of ventilation. There are some cases in which natural ventilation is rather unsatisfactory, but for all ordinary requirements it is an excellent system.

The Bristol Sewage Bill has been rejected by the ratepayers on a poll by a vast majority.

Sawmill Strike at West Hartlepool.—The strike of workmen employed at Messrs. Harrison and Singleton's Baltic Sawmills, which commenced last Saturday week, has been settled, the men resuming work last Friday.

Lady Sanitary Inspectors.—Two recommendations of the Public Health Committee came up for discussion at last week's meeting of the Edinburgh Town Council; one was for the appointment of two qualified female assistant sanitary inspectors, and the other for the appointment of four additional male assistant sanitary inspectors. (Of lady sanitary inspectors Liverpool has eight, Leeds two, Manchester two, Sheffield two, and St. Helen's one.) The first recommendation was rejected by the casting vote of the Lord Provost; the second was agreed to unanimously.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.	WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDER MAY BE OBTAINED.
BUILDING—			
Feb. 9	Rugby—Post Office	H.M. Office of Works	Office of Works, Storey's Gate, S.W.
9	New Brompton, Kent—Houses		F. Smith, Architect, Bank-chambers, New Brompton.
9	Cemaes, Isle of Anglesea—Coastguard Buildings	Admiralty	Director, Works Department, Admiralty, London, W.C.

Messrs. FAREBROTHER, ELLIS, and CO. publish in the advertisement columns of "The Times," "Standard," and "Morning Post," every Saturday a list of their forthcoming Sales by Auction. They also issue on the first of every month a schedule of properties to be let or sold, comprising landed and residential estates, farms, freehold and leasehold houses, City offices and warehouses, ground-rents, and investments generally, which will be forwarded free of charge on application.—No. 29, Fleet-street, Temple Bar, and 18, Old Broad-street, E.C.

A MAGNIFICENT FREEHOLD, RESIDENTIAL and BUILDING ESTATE for DISPOSAL, situate five minutes from a station, in a favourite position, only thirty-five minutes from town, and having extensive main road frontages; the well-timbered park lands of over fifty acres are immediately available for independent development, and can now be obtained at a low price of £250 per acre, and will be worth double in the course of a few years. The mansion and stabling and very extensive grounds are in first-class order for immediate occupation, boating, fishing, and golf are near at hand, and the acquisition of this property presents an opportunity for residence, combined with profitable investment, seldom to be met with.

Full detailed particulars and plan will be forwarded to intending purchasers or their solicitors by the Owner's Agents, Messrs. GEORGE TROLLOPE and SONS, 14, Mount-street, W.

R.I.B.A. EXAMS. PREPARATION, personally or by correspondence, in three, six, nine, or twelve months' courses. Architectural Lending Library. Special three months' finishing courses.—For full particulars apply to Messrs. HOWGATE and BOND, Associates R.I.B.A., 115, Gower-street, W.C. (close to the British Museum).

MODELS.

For Exhibitions or Law Cases. Illustrations sent of Work Executed. JOHN B. THORP, 98, Gray's Inn-road, W.C.

R.I.B.A., Society of Architects, and Civil Service Technical Examinations. Personal, correspondence, or resident preparation. Seventeen first places.—MIDDLETON and CARDEN, Associates R.I.B.A., 19, Craven-street, W.C.

GERMAN ILLUSTRATED ARCHITECTURAL PAPER will be glad to PUBLISH Drawings and Plans of British Buildings free of charge, returning blocks franco. Architects desirous of publishing designs apply to Box No. 1292, BUILDERS' JOURNAL Office. 1

WOODWORK.—A thoroughly equipped Workshop, having railway siding and water frontage, first-class British and American tools, capable manager and workmen with many years' experience, OPEN TO EXECUTE ORDERS for any class of woodwork, in the rough or finished either to model, drawing, or specification. Large stock of thoroughly seasoned wood always on hand.—Apply DALMUIR, care of BUILDERS' JOURNAL. 1

APPOINTMENTS VACANT.

ARCHITECT'S ASSISTANT (competent) WANTED.—Write, stating age, experience, and salary required to CARTER and ASHWORTH, Architects, 86, Eden-street, Kingston-on-Thames. 3

BUILDER'S CLERK WANTED (experienced). Permanency for a good man. State full particulars and salary expected.—Address, "BUILDER," "Observer" Office, Lancaster. 1

APPOINTMENTS WANTED.

The charge for Advertisements under this heading is 1s. 6d. per insertion not exceeding four lines, and 6d. per line afterwards, prepaid. Three insertions may be had for the price of two.

YOUNG ARCHITECT, A.R.I.B.A., ASSISTS in the PREPARATION of DRAWINGS, TRACINGS, &c., at his own Office. G. SCORER, 28, Newman-street, W.

SANITARY INSPECTORS' EXAMINATIONS.—An Associate of the Sanitary Institute thoroughly PREPARES CANDIDATES for the above Exams. by correspondence; no books are required.—For particulars and testimonials apply, "Certified Coach," "Malabar," New Eltham, S.E. 11

PLUMBER'S IMPROVER requires job; used to City Jobbing Shop; wages, subject to arrangements.—G. L., 21, Greenville-street, Victoria Docks, E. 1

QUANTITIES.

H. B. JOHN, P.A.S.I.
TUDOR VILLA, TUNBRIDGE WELLS. 1

CIVIL ENGINEER, experienced in drainage work, building construction, &c., wishes for EMPLOYMENT anywhere in United Kingdom; clerk of works, or any post offering; moderate terms; good testimonials.—Address CHAS. CRAWCOCK, C.E., 29, Argyle-square, King's Cross, London. 1

Important to Architects.

It often happens that in addition to preparing plans for the erection of a public building or private house, an architect is called upon to carry out a scheme of interior decoration and furnishing.

In order that this may be done satisfactorily it is necessary to take into consideration the style to be adopted in relation to the architecture of the building treated, and also the schemes of colour and materials to be used in the decoration of surfaces.

Formerly the difficulty has been to find an authoritative publication which would be a reliable guide to those engaged in this branch of the profession, and one which would introduce new ideas for interior decoration in addition to keeping a record of all the novelties introduced by the manufacturers of furniture and fittings.

*The proprietors of the "Builders' Journal" have therefore pleasure in directing the attention of the profession to their new monthly publication **THE FURNISHER**, which deals exhaustively with all branches of the furnishing trades. This publication is divided into sections dealing with "Furniture and Upholstery," "Decoration," "Metal Work," "Lighting and Heating," "Pottery, China and Glass," and "Silver and Electro-plate." Each issue contains original designs and suggestions by well-known modern designers, and plates are given from time to time, with examples of the best work of some of the older schools. The journal is printed on superior paper, and illustrated in first-class style, and is worthy of the attention of all who have in any way to deal with the furnishing and decorating of public buildings or private dwellings.*

PUBLISHED ON THE 15th OF EACH MONTH.

City Fountains.

MANY years ago, in the pages of "Little Dorrit,"

Charles Dickens said of

the British travellers in Rome, that all their opinions were borrowed and everything was artificial except the water which rushed and bubbled "from its glorious multitude of fountains." Not every city is so favoured in that particular, for a number of streams flow down from the hills, and, crossing the Campagna by the great aqueducts, so enter the town. Paris, again, boasts of a considerable number, and there are few continental cities which do not make ornamental fountains a conspicuous feature in their embellishment. Brussels has recently erected one to the memory of Baron Anspach in the Boulevard of that name, and its design is worth recording. The bust of Anspach is placed at the foot of a small obelisk of porphyry, which rises from the upper of two basins; these appear to cast water at each other up and down from many jets placed outside the rims. There is no central jet, its place being occupied by the obelisk. Outside all is a mass of flowers; the fountain seems to be embedded in them. There is no pleasanter way of enlivening and refreshing a modern city, no more satisfactory object to fill the centre of a square or of a space where four streets meet, than this. But London has little to show in the way of fine fountains. The two jets which rise in Trafalgar Square from plain unornamented basins are not important enough for the site; they barely suffice to break up the granite desert about them, and the lack of fine detail and of surrounding greenery, their want of scale, and the absence of any effective grouping in the statuary about them, provide an object lesson in the art of "how not to do it." A Parliamentary committee alone could have devised anything so tame and formal; an architect, given a free hand, could soon produce a better arrangement of this, the most conspicuous square in London. At Sydenham, indeed, a series of stately terraces lead to some fountains on the scale of Versailles, but Sydenham is a long way off. The Shaftesbury Memorial Fountain, in Piccadilly Circus, is notable for its design and a little fine detail, but, as almost invariably happens in London, the frame of the picture has not been considered, and the structure requires to be grouped with surrounding objects; the removal of one-quarter of the Circus has not improved matters, for the converging streets now end "in the air;" finally, the fountain is neglected and very dirty, a discouraging fact to the artist of the future who wishes to emulate Mr. Gilbert. An attempt was made as far back as 1862 to introduce a new material for ornamental work in London. This was the once famous Majolica Fountain, which was so prominent an object in the International Exhibition of that year. Its bright colour and the apparent insensibility of the majolica to the destructive London atmosphere were much and favourably commented upon at the

time, but the experiment was never repeated, and the structure eventually found its way to the Bethnal Green Museum, where it now stands facing the main entrance. The whole subject of street and open space designing is constantly being reopened as London is rebuilt, and in view of the general mildness of our climate and the very hot summers of recent years, the question of more fountains is one that Londoners might consider with advantage.

J. C. P.

London's New Railway Stations.

THE Central London Railway, which was to have been opened

this month, is not yet so far advanced, and if we see this welcome addition to our very inadequate methods of locomotion in London inaugurated by May next it is as much as we really can hope for. There are a goodly number of subterranean electric railways for London in various stages. Some are under construction, and some have obtained Parliamentary powers, but have hitherto failed to secure the necessary capital, while others

Southwark to Moorgate Street, and from Stockwell to Clapham, are being constructed, and it is understood that the Moorgate Street to the Angel, Islington, section will shortly be commenced. To these must be added the five projected stations for the Great Northern and City, now being pushed forward by Sir Weetman Pearson's firm, and the five on the Baker Street and Waterloo Line, whose works are prominent at Charing Cross.

The Piccadilly Circus and Brompton Railway, whose powers were granted two years ago, does not appear to have secured any financial support, and so the two stations which it would have had do not seem likely to appear as rivals to the omnibuses; nor has anything been heard of late respecting the projected deep level electric line projected by the District Railway to run beneath the existing rails from Mansion House to Earl's Court, with an intermediate station at Charing Cross. Although, however, certain of these schemes appear to be in a state of suspended animation, it must not hastily be concluded that they are therefore dead. On the contrary, some of the hoary old projects which date back some twenty years—before, in fact, the days of electrical enterprises—

COTTAGE AT CASTLE BROMWICH, FOR LORD NEWPORT. BATEMAN AND BATEMAN, ARCHITECTS. (See p. 19.)

yet are in the merely inchoate state of being just engineers' and financiers' schemes that have not hitherto been drafted into Bills for the consideration of Parliament. In the aggregate, all these various competitors with the omnibuses for the twopences and the threepences of Londoners will total up a number of new metropolitan railway stations which, until analysed, seems almost incredible. Let us, however, essay the task of detailing them. To begin with the Central London, the longest and the most important of all, occupying, as it does, the line of the main artery of traffic between east and west, from Shepherd's Bush to the Bank: there will be no fewer than fourteen stations on these four and a-half miles alone. On the Hampstead, St. Pancras and Charing Cross line, a duly authorised project whose powers have already been once renewed by Parliament, but which is not yet in course of construction, there will also be fourteen stations. On the authorised extensions at each end of that pioneer among London electric railways, the City and South London, there will be eight. These extensions, from

appear likely to be revived. Of these, the long-talked-of "North Metropolitan," whose powers were several times renewed and eventually allowed to lapse, may yet come to fruition. This speculation we are induced to indulge in on reading between the lines of certain authorisations now sought in Parliament by those new and oddly assorted allies, the Great Western and the Great Central Companies. The "North Metropolitan," originally named the "Regent's Canal, City and Docks Railway," was a pet project of that very strenuous person, Mr. James Staats Forbes. There would have been no fewer than fifteen stations on the twelve-mile course from Paddington to Limehouse, along the route of the Regent's Canal. But the many millions required from the public for the financing of that undertaking formed too big a lump for investors to find, and so the idea lapsed perhaps for others to take in hand. Apart from this problematical revival, the new London railways will give us forty-seven new stations, and not even then will London's needs be wholly met.

C. G. H.

THE "BUILDERS' JOURNAL"
SHILLING FUND.

TO ERECT HOMES FOR DIS-
CHARGED SOLDIERS.

OUR fund was started with the object of assisting in the erection of the proposed Soldiers' Homes at Bisley, which are to form the building trades gift to the nation, and especially of enlisting the help of those who could not send substantial cheques or gifts of building materials. This special object we are glad to say is being, to a great extent, accomplished, and if the BUILDERS' JOURNAL Fund fails to reach a colossal total it will at least succeed in gathering in the small gifts of many who, in all probability, would not think it worth while to contribute direct to the central fund. In this way we shall assist what is undoubtedly one of the main objects of the scheme, viz., the inauguration of a national gift which shall be thoroughly representative of the building trades, the result of a widespread co-operative movement embracing all classes who are in any way connected with these trades.

Some Gratifying Letters.

It is very gratifying to find that the collecting forms we have issued are being largely made use of in the way we desired; that is to say, they are being circulated in offices and workshops and returned to us filled in with many small contributions. We shall be pleased to send these forms to any reader who will thus put them to good use. Here are two letters which show the admirable spirit in which the scheme is being taken up in some of the builders' workshops:—

CHELMSFORD. Feb. 7th, 1900.
Gentlemen,
I have much pleasure in sending you cheque for 38s. 6d., collected by me on the form enclosed in my BUILDERS' JOURNAL. The appeal was readily responded to by all. Wishing you every success in a cause worthy of the building trade, to which trade I feel it an honour to belong,
Yours respectfully,
R. BROOKHOUSE.
(Builders' Foreman.)

HORLEY (SURREY). Feb. 7th, 1900.
Dear Sirs,
Herewith I have very great pleasure in forwarding the accompanying amount, viz., £2 14s. 0d., on account of the fund being raised on behalf of the Soldiers' Homes, which is a most worthy one. [Wishing you every success in your undertaking.
Yours faithfully,
C. E. DAVIS,
(Clerk of Works.)

A Word to Architects.

While these encouraging efforts are being made by builders and their employes, we are bound to confess to a certain measure of disappointment at the comparatively small response which architects have made to our appeal. Some few, indeed, have responded most generously, notably Mr. H. L. Florence, F.R.I.B.A., who sent us a cheque for £10, but the profession generally has not yet taken any considerable share in this most worthy enterprise. Yet the fact that an appeal is being made to builders and contractors for gifts in kind might lead one to suppose that the bulk of the money contributions would come from the architects. Doubtless many architects have already contributed to one or other of the many patriotic funds that have been started since the war began, but we hope they will, nevertheless, feel it incumbent upon them to take some share—if only by sending a few shillings to the BUILDERS' JOURNAL Shilling Fund—in a work which is so closely identified with their profession. Are there not among the younger men—the assistants and students—many who might, with a little personal effort, materially swell the fund by collecting shillings from their friends and associates? Hundreds who would not take the trouble to send off a donation by post would willingly give a shilling if asked for it.

The following list of subscriptions includes all sums received up to last Monday afternoon:—

Other Contributions.

We published last week a full list of contributions in kind, for which promises had been received at the offices of the Executive of the Building Trades' Gift. Just as we go to press we receive from the chairman of the executive the following further list, showing that a large number of additional contributions have come in since the publication of our first list. Notable among these is the very handsome donation of 750,000 stock bricks from Messrs. Eastwood and Co., Lim. This, we understand, constitutes the whole of the stock bricks (facers excepted) wanted for the whole of the buildings.

FOR THE ENTIRE SET OF BUILDINGS.
Messrs. Eastwood and Co., Limited.—750,000 Stock Bricks for the whole of the buildings.
Messrs. Pilkington and Co.—Asphalte Paving under floors throughout.
FOR INDIVIDUAL SECTIONS OF THE WORK.
Messrs. W. H. Lorden and Son (Upper Tooting).—twelve Window Sashes and Frames.
Messrs. E. and C. Braby.—1,000 feet super. of Opal Tiling.
Messrs. Dent and Hellyer.—Sanitary Fittings for one Home.
Messrs. Stephens, Bastow and Co. (Bristol).—forty Doors.
The Sub-Wealdon Gypsum Company (Robertsbridge, Sussex).—25 tons S rapite Plaster.
Messrs. Fredk. Braby and Co.—1,600 square feet of zinc roofing.
The Poole Steam Joinery Works (Poole).—The architrave mouldings for one Home.
Messrs. J. and F. Gridley (Woking).—The Slate battens for three Homes.
Mr. B. E. Nightingale and Workmen.—Staircase for one Home.
The Lift and Hoist Company.—A service Lift.
Messrs. Durrants' Gully Company.—Twelve Patent Road Gullies.
Messrs. J. W. Falkner and Son.—Forty Doors for one Home.
Messrs. Cartland and Sons (Birmingham).—Four sets swing centres.
Messrs. W. W. Howard Bros. and Co.—£25 worth of wood materials.
Messrs. McTear and Co. (Belfast).—Roofing felt for three Homes.
The Festiniog District Slate Quarry Proprietors Association (Merioneth) (Per Mr. John George Ashmore).—10,000 Portmadoc Slates.
Kensington Blind Works.—Outside Blinds for one House.
Messrs. Malcolm, Macleod and Co.—1,000ft. of granite paving.
Messrs. Burt and Potts.—Metal Casement Windows for ground floor of Recreation House.
Mr. Thomas Faldo.—Vertical Damp Course for three Service Blocks.
Messrs. Burke and Co.—Tiling for varandahs and connection corridors.
Mr. John Marsland.—Six Dwarf Cupboards.
The Patent Victoria Stone Company.—100 feet cube Victoria Stone for entry steps.

Altogether it is evident that the members of the building trades are determined to make their special gift one of the most noteworthy and admirable of the many demonstrations of patriotism which the South African war has called forth.

"THE HOMESTEAD," WOODBOURNE ROAD, EDGBASTON. BATEMAN AND BATEMAN, ARCHITECTS.

Men Who Build.

No. 58.

MESSRS. BATEMAN & BATEMAN.

THERE are surely very few architectural practices in this country which can boast such long established traditions, and so remarkable an ancestry, as does the distinguished Birmingham firm whose work is the subject of this article. Indeed, before ever Birmingham gave promise of swelling to any such importance as now attaches to it, and before any conjecture could be formed of its present growth in culture and commercial activity, or of its attaining the importance and notoriety which now attaches to the city, the name of Bateman was, and has remained, one of the most conspicuous in the architectural history of the place. For three generations the mantle of the father has fallen in succession upon the son, and from generation to generation the traditions of the firm have been modified with the changing ideals and needs of the life of the time, till in the work of the present firm we may observe just that analytical, virile, inceptive attitude towards architecture which is at once the distinguishing quality of the best inspired impulses in the applied arts of the present day, and in diagonal antithesis to the tradition-worship which held all practitioners of architecture enthralled scarcely so long as sixty years ago. How far back reach the traditions of this firm, and of how modern a growth is Birmingham as we now know it, is vividly brought before the mind by many reminiscences of the conditions under which the early work of the firm was done. Thus it is on record that at the time Mr. Joseph Bateman, the grandfather of the present acting representative of the firm, began to establish the practice, the site of the old town hall and present art gallery (which in the first steps of a picturesque decay seems to the casual visitor to be one of the old landmarks of Birmingham) was, with its vicinity, laid out in meadows which had a local celebrity for the rabbits to be taken there. It is said that Congreve Street, lying behind the art gallery, owes its name to this old association of the place. Even the present senior partner of the firm, Mr. John J. Bateman, who still takes an active

part in the business, can remember how in the early days of his professional career he was once employed in assisting to do certain work that had been occasioned by the damage wrought by the mob in Birmingham at the time of the Chartist agitation.

The illustrations appearing in these pages show refinement, reserve and a great resource and enthusiasm in their design, and include public buildings, business premises, mansions, small houses and cottages, in all of which these same distinctive characteristics of enthusiasm and imagination and unimpeachable good taste are manifested. Mr. Charles E. Bateman, F.R.I.B.A., the junior member of the firm, with whom, as acting partner, the firm's designs are now gradually becoming personally associated, is reading a paper before the Architectural Association next March upon small houses, and no doubt we may then have an opportunity of examining a type of plan to which the whole profession has, of late

years, given a great deal of attention, and in the management of which Mr. Bateman has been particularly successful.

The three views of Vectis Lodge, and those of the Gable House and the cottage at Castle Bromwich are interesting, if not the most characteristic specimens of his work. A small house, as is well exemplified in Messrs. Bateman's designs, is—its inside. It may truly be said it begins and ends with that. An elevation which arises from a compact and convenient plan, and which accentuates the position and uses of its two or three reception rooms, will require little but a tasteful choice and usage of material, and a slight accentuation of predominant features to give it a finished appropriateness and the charm of perfect fitness which, in a small house or cottage, no architectural "forms" or accessories can dignify or embellish. The design of a small house is only to be presented by carefully detailed plans

THE GABLE HOUSE, KINGS HEATH, WORCESTERSHIRE. BATEMAN AND BATEMAN, ARCHITECTS.

VECTIS LODGE, EDGBASTON. BATEMAN AND BATEMAN, ARCHITECTS.

which show ingle-nook, seat, dais, cupboards, and exemplify all the minute forethought which must be expended in fashioning a small house which is to be lived in without the great discomforts of a small house. In a mansion, or a large house, entirely other issues are to be considered, but in a small house there is little more to be solved when the great difficulty of convenience and compactness has been vanquished with success. For this reason internal perspectives cannot do justice to such designs, even if the distortions incidental to the method are nullified. If a small room is perfectly convenient it is essentially beautiful, unless marred by bad colour or decoration, but neither perspective drawing nor photograph can give an inkling of this refinement of convenience which constitutes the true excellence of a design; what the drawing and the photograph succeed in conveying and idealising is the picturesque

and bijou qualities of the building, which are precisely those qualities which mar the efforts of those who design small houses, and are such as should make every sensible person extremely cautious and distrustful of having an architect's small house fobbed off upon them. There is much to be said on all scores, both of science and art, against the ordinary British middle class family abode:—a hall door and a bay window; a square drawing-room and a square dustbin; a passage leading from the drawing-room to the dustbin, and a smell of cooking in all three; but on the other hand there is a commendable sturdy lack of sensibility in this British abider, and his distrust of a certain impossible dandyfied elegance in the small houses of many of our architects is eminently healthy, and the instinct is eminently salutary for the morals and stolid traditions of the nation. After all, people live their lives as fully in a small house as in a mansion; indeed the realities of life—its tragedy, pathos, heroisms and full sweetness—are not so commonly the experiences of the affluent and independent as of those who are popularly considered less fortunate. Nearly all small houses are tricked out in a way which might perhaps be considered reasonably fitting in a Kensington flat "to be let" for "the season," but how are we to associate the dignity attaching to a home, and the full sentiments of human life with its joys, sorrows, and mysteries, with surroundings such as would cause the ordinary woman to throw up her hands and exclaim, "*Oh! how sweetly pretty!*"

It is not to be understood that these remarks have any particular reference to the work of Messrs. Bateman and Bateman. Indeed, as the practitioners of this phase of architecture incline, Messrs. Bateman and Bateman are distinguished for simple unaffected plans. It is, however, almost inevitable in a small house where the few features have a special prominence and call for special treatment, and the actual smallness of the various parts must be disguised as far as is possible, that it should be extremely difficult to keep a uniform scale throughout the building without breaking it up and procuring a *bijou* effect, which, when strongly marked, is much to be depreciated.

There is one experiment which Messrs. Bateman have made of late years which is deserving of wide consideration, and which, if

their examples should be followed at all generally, will be likely to arouse a good deal of theorising and debate in professional circles. The circumstances under which it is rightly applicable, however, do not very commonly arise. We refer to the use of old material in a new building. Some years ago an old mill was pulled down at Castle Bromwich, near Birmingham, and at that time Messrs. Bateman holding a commission to build a block of two small houses on Lord Bradford's estate hard by, and the design having the general

VECTIS LODGE, EDGBASTON. BATEMAN AND BATEMAN, ARCHITECTS.

character of a cottage, they secured the sound bricks from the *débris* of the mill and built the houses with them.

The bricks were old, and were the ordinary bricks obtainable at the time the mill was built, and what were the weather sides and ends of the bricks as laid in the mill do not appear in the walling of the cottages. To what is due the unquestionable charm of colour, and, more particularly, of texture, in Messrs. Bateman's building, it would be hard to say. It is certainly not due to any special quality of colour or substance in the bricks, which were originally of that mottled salmon red and grey which is generally associated with common bricks and is universally tabooed for facings when any choice can be made. The success of the walling must chiefly be due to the texture of these bricks. They were originally rough bricks, and from handling and being cleaned of mortar with the trowel, have been made rougher again, although the bricks laid as facings are always sound and square. Messrs. Bateman have had them laid with a wide white flat-pointed unstruck joint, and the result must have satisfied their most sanguine conjectures. Judging from this building, which is finished with Bath stone copings and dressings, any architect may avail himself of old brickwork with perfect confidence provided the design does not demand a smooth and equal texture in the walling, and sharp arrises. That bricks may be used thus in buildings quite other than those having the character of cottages is exemplified by the premises of the Birmingham Guild of Handicraft, in which Mr. Arthur Dixon, whether in imitation or of his own initiation, has used bricks from the walling of a demolished building with equal success, if not with the peculiar appropriateness which marks Messrs. Bateman's design. It should here be remarked, lest the reader should get an impression that the use of these old bricks produces an effect of old brick walls in the new building, that such is not in any way the case. It is possible that in fifty years such brickwork might impress the beholder as being a hundred years built, but in neither of the designs referred to is the part of the

INTERIOR, VECTIS LODGE, EDGBASTON. BATEMAN AND BATEMAN, ARCHITECTS.

freshness of the building disguised, nor can the method be considered economical except under particular circumstances. It may be mentioned that Mr. Bateman and his son have now made their home at Castle Bromwich in one of these same houses.

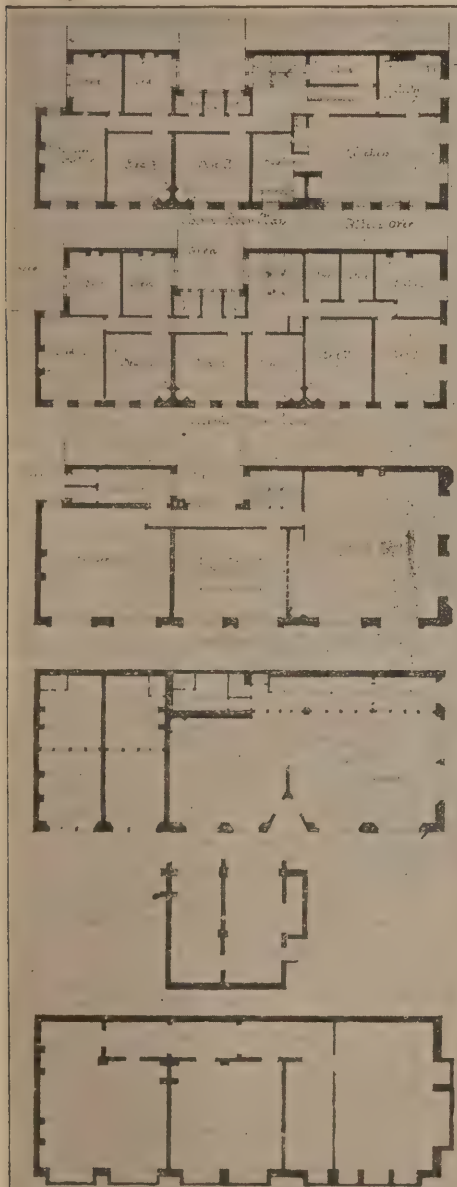

While mention is being made of Castle Bromwich, a word may fittingly be said of the church. In this connection Mr. Charles Bateman made an incursion into archæology which must have put local chroniclers to the blush, and which certainly added a valuable chapter to the history of the locality, and forms an interesting note to what we know of church restoration and adaptation in the last century, or to be clear of ambiguity—in the eighteenth century. To state in a few words what is set forth at length in his illustrated monologue on Castle Bromwich Church, he discovered, and was finally able to reconstruct in plan and section, a wooden church with oak pillars and half-timbered walls which was cased and enclosed by the somewhat gloomy Renaissance church, and which had remained completely lost and unknown. It must seem an extraordinary fact that though complete and in actual existence little more than a hundred and fifty years ago, there was no record of what had become of the old building, and its existence was entirely unknown until Mr. Bateman's exhaustive survey revealed these curious and interesting facts.

Some of the earlier buildings erected from the designs of Mr. J. J. Bateman are the Birmingham workhouse; the Manchester and Inns of Court hotels, London; the Church of the Messiah, in Broad Street, Birmingham; St. Cuthbert's Church, Winson Green; and churches at Tettenhall Wood and Water Orton. For the Corporation of Birmingham he designed the branch free libraries of Gosta Green and Deritend and the fish market; and for the Corporation of Dudley the free library, school of art, and art gallery in that town. At Rugby the George Hotel and Club House, and additions to the school and masters' houses for the late Dr. Tate, were erected from his designs, and at Leamington a bank. Of buildings in Birmingham may be mentioned Queen's College; Messrs. Hyam's and Messrs. Osborn's premises in New Street, 57, Colmore Row, and Church Street; the Quadrant; Swan Hotel, shops, and Messrs. Turner's premises in Worcester Street; the Hockley and Balsall Heath dispensaries; and a large number of manufacturing premises. In domestic work he is represented by Stechford Hall, Gilbertstone; Ashwell Hall, Oakham; and numerous houses round Birmingham and in the country. Some of the above works were carried out in conjunction with Mr. B. Corser.

Since Mr. C. E. Bateman joined his father the following works have been executed:—Messrs. Hinks' premises in Charing Cross

Road, London; The Cedars, Calthorpe Road, Edgbaston; No. 3, Cannon Street, for the "Birmingham Daily Post"; 154, Great Charles Street; a colony of houses at King's Heath; Brass Foundries, Constitution Hill and Leopold Street; premises in Cannon Passage; Glass Works, Stourbridge; the Birmingham District and Counties Bank, Broad Street; gun factory for Messrs. Westley Richards and Co.; The Homestead and Vectis Lodge, Edgbaston; and houses at Barnt Green, Coventry; Hampton-in-Arden; Abergavenny, and Langham, Oakham; also decorations, fittings, tablets, &c., in King's Heath; St. Mary's, Birmingham; Water Orton; Dunston; Stoke; Salkeld, Derby; Walsall; and other churches.

The Dover Works.—The first block recently laid in connection with the Government defensive works at Dover Harbour by Messrs. Pearson and Sons, the contractors, weighs forty tons and is one of the immense blocks of stone and concrete being manufactured by them on the Stour marshes, outside Sandwich. Those desolate flats are now occupied by the contractors, who have laid down a special railway and got together a huge plant, utilising the wastes of shingle and the unfathomable mud of the mouth of that sluggish river as the raw material for the concrete.

The Cannon Street Hotel Birmingham.

ARCHITECTURAL ASSOCIATION.

WORKING CLASS DWELLINGS
IN BLOCKS.

By THOMAS BLASHILL, F.R.I.B.A.

At a meeting of this Association held last Friday evening at No. 9, Conduit Street, Regent Street, W., Mr. G. H. Fellowes Pryne, the president, in the chair, the following gentlemen were elected members: C. Brett, D. A. Forster, W. T. Loveday, H. Redfern and J. G. Walker. The president said he hoped that members were competing for the prize for measured drawings offered by the Architectural Union Company, which some time ago Mr. Arthur Cates had announced, at the request of the company, would be withdrawn unless more interest was taken in it. The committee of the Association then had requested that it would be of use to have a subject suggested. This had now been done as an alternative subject for those who might not have already prepared drawings, and this suggested subject was a study of four tracery windows illustrating the development of tracery, consisting of a half interior, including wall arching and a half exterior of each window drawn to a lin. scale showing the jointing, full size details to be given in each case and the original measured sketches to be submitted. Mr. Thomas Blashill then read his paper on "Working Class Dwellings in Blocks" as follows:—

The invitation to read this paper recalled to my mind an occasion long ago when the Association devoted an evening to the same question. On November 13th, 1863, Mr. H. A. Darbyshire, who was then and afterwards largely concerned in this kind of work, read a paper "On the Construction of Dwellings for the Poor," and I, being then the immediate past President, took part in the discussion. Mr. Darbyshire, who gave us much useful information, began by saying that the subject was full of interest, and in skilful hands might be treated with novelty, but, as it had been so much discussed, he had little hope of giving additional information or enlightenment in the quarter of an hour which he proposed to occupy with his paper. One reads this with a melancholy interest after an interval of six-and-thirty years, during which, in spite of the work done by the author of that paper, and in spite of all that has been done by societies, by private individuals, and by the public authorities, the housing question is even more than formerly a matter of serious concern.

There are many well-meaning persons who shudder at the mention of a block or barrack building, desiring to see our working classes housed in two-storey cottages behind gardens, leafy, floral, and rustic fenced. In theory I agree with them, but the practical man must recognise that when the middle class has taken so kindly to "mansions" or "flats," it would be waste of time to argue against the housing of a working-class family in a "dwelling" situate in a block.

The great difficulty which faces the working man who must live near the centre of a town is the increasing scarcity of land that is suitable for him, but not capable of being used in more remunerative ways. To this must be added the increasing cost of building, and they inevitably lead to an increased outlay on rent. All we can do as architects is to exercise the most rigid economy in planning, in fittings and in finishings, with a good deal of reserve in the design of elevations. Besides this, ordinary materials and articles must be used in ordinary ways. An opportunity of designing a working man's dwelling is not the occasion for experiments which might be tried, in his absence, in the house of a colonial millionaire. This has always been the besetting sin of the designer of "model" dwellings. In some published designs, probably the best at their date, the houses were to be constructed with special bricks that would have to be laid by specially trained bricklayers; there are special drain-

pipes and special window casements, with floors of a costly and uncommon fireproof construction, finished, even in the bedrooms, with a smooth vermin-proof surface of Portland cement. Looking candidly at these designs, they do not seem suitable for working people of any known kind. The population, like the buildings, would have to be special and "purpose made." We must consider what these people are accustomed to, what they want, and what they can afford.

I suppose the bulk of the families for which new dwellings are required are now lodging with other persons of about their own class, or take rooms in houses that are let out in tenements. All that is private to them is the bare rooms. The scullery or washhouse, the closet and dust-bin, are used in common and with much less inconvenience than one might expect. The people are satisfied with such arrangements, and the families are helpful to each other. Directly you provide a complete dwelling that cuts off family from family, difficulties arise before unknown. Everything must be private and special to each family. If you imitate the old-fashioned arrangements by providing adjuncts to be used in common, extra supervision is necessary, and this is a serious item of expense.

Then points of "hygiene" not raised by the working man, not appreciated by him, to some of which he is bitterly opposed, and for none of which he will willingly pay, come into prominence. Ventilation is his horror when it takes the form of staircases exposed to the air, thoroughly ventilated lobbies, or anything that causes movement of air in or about the dwelling. These are points on which you cannot argue with a medical authority; he is doubtless right, but if you design your workmen's dwelling in every respect on his lines it will probably not be occupied by a working man. There must be some point short of absolute perfection with which a reasonable man may be satisfied and beyond which we need not insist upon forcing our ideas, however defensible they may be, upon people whose risks of starvation and of being turned into the street admit of no dispute.

In the first place, I should not be so fastidious in the matter of site, subsoil, and surroundings as a Government inspector might be in the case of a hospital or a gaol; your occupiers will not be patients or prisoners. Make the aspect of the principal rooms as good as you can and strictly obey the Building Acts and Public Health Regulations, trusting to the general outdoor habits of the people and to their common sense for the rest.

Let us assume that your block can only be lighted by windows at front and rear. It may be so designed that the plan can be repeated down the whole length of a street. It is generally better that entrance to the staircase should be at the rear. This gives the tenants direct access to the playground, and keeps off the loafers and criminals who, in certain localities, infest staircases accessible to the street. If there is a choice, it is generally better to put the living rooms overlooking the street; but upon this point, and others of the like kind, the important thing to the working man is to get a dwelling, let the aspect and the prospect be what they may.

Get into early communication with the district surveyor and the local public officers and fully explain your proposals; they will save you much after trouble and may give you sympathetic help. Do not be tempted to threaten that if they will not pass a certain arrangement on which you have set, your heart you will find lawful means of doing worse.

A block dwelling will usually consist of four square storeys with a Mansard storey in the roof. You will want 40ft. clear open space in front, and, subject to the Building Act, as much as you can get in the rear. A sixth storey would probably let well, but will require thicker walls and more open space. A lower building will hardly pay for the cost of foundations and roofs.

The ground floor level should be a foot at least above the back of the footway pavement; sometimes a half-basement is made but the front area and the whole of the open space at rear should then be sunk below the level of

the floor. Each storey will be 8ft. 6in. high in the clear. The staircase should be 6ft. 6in. to 7ft. wide for the two flights.

The floors of rooms should be made at least "fire resisting." Pugging between the wood joists would be sufficient, but all the floors in the dwellings put up by the London County Council are made of coke-breeze and cement carried by steel joists. They are thinner than wood floors, saving a course of brickwork in all walls, and we found them somewhat cheaper; but this must depend on the price of steel. Care is required in mixing the coke-breeze concrete and in applying it so as to be firmly held by the flanges of the joists, which should be rather wide. I advocate here fire resisting floors for convenience of construction as well as cheapness, but fires in these block dwellings hardly ever extend from one room to another whatever kind of floor is used. Extension of fire from one tenement to another is almost unknown. The concrete under the ground floor has a covering layer of coke breeze and cement concrete and all floors have thin floor boards nailed down close on the coke breeze after this is quite dry.

Some useful hints may be gained from the particulars issued by the London County Council a few months ago for designs for blocks on their Millbank Estate; but these must be used with discretion. The Council, having expended about £50 per head of all the persons removed from insanitary areas, stipulates that the new buildings shall be so designed as to let, without further loss to the Council, at the rents that rule in the neighbourhood. They have to pass very strict medical criticism. One result is that the tenements are made very complete in their arrangements and the rents are beyond the means of the persons turned out. I am afraid that any really good complete sanitary dwellings will get into the hands of those who are comparatively well off, and not till this class has been satisfied will the working man of small earnings have his turn.

In the competition the Council demanded through ventilation from front to rear of each tenement, no back-to-back dwellings being allowed. The staircases were to have horizontal ventilation through windows opening direct to the open air. The average area of living rooms must be 160ft. superficial, that of bedrooms 110ft. If two bedrooms were provided, one must have an area of 120ft. No living room was to be less than 155ft., and no bedroom less than 100ft. This is very good, but the usual size demanded for a living room has been 144ft. and for a bedroom 96ft., which are the dimensions given to us by Mr. Darbyshire. In many modern cottages such rooms are only 120ft. and 60ft. or 70ft., and I am not aware of any serious mischief that has arisen from these small dimensions where other things are satisfactory. No bedroom must be connected with any other bedroom, and in general these are entered from the living room.

A dwelling should consist of a living room with one or two bedrooms—sometimes a third. The inmates will be reckoned at two persons per room, and no doubt the living room will be used by night as well as by day.

Dust-shoots, by the County Council conditions, are not to be provided, but each tenant will have a dust-pail, and there will be a dust-bin in the common yard into which pails may be emptied at any time. I determined from the first to have no dust-shoots in the Council's dwellings. They are unwholesome in themselves, and they involve an underground chamber that for many days together is filled with decaying vegetable and animal matter, and is difficult to empty without nuisance. The parishes met this idea in different ways, but all fell into the idea better than I had expected, their men collecting the pails either in the yard or at the doors of the dwellings. But some architects of experience prefer the dust-shoot. Each tenement must have its own scullery and closet. Washing or drying accommodation was demanded by the Council, but not baths; and some arrangement must be made, perhaps in connection with a caretaker's lodge, by which the tenants could draw hot water for tea or for early breakfast. Food cupboards were not demanded.

Bearing in mind such conditions as these, so far as is practicable, we may proceed to consider the kind of dwelling that can be designed with reasonable expectation that it will be inhabited by the working man. Upon this point I may be permitted to say a word about the designs which were submitted in this competition. It was clearly laid down that the buildings must involve no charge on the rates, so that every outgoing which the Council would have to meet must be paid out of the rents. Some competitors showed covered playgrounds which occupied the place of rooms, and other luxuries, all very nice, were thrown in. All the designs were far too costly in plan or in elevations, or both, and for that reason none could be carried out.

The working man's dwelling is divided sharply from that of the ordinary clerk and from the "flat" by having no accommodation for a servant. It is inhabited by the family only; they wait on themselves and on each other. We may classify the usual kinds of block dwellings in this way:—

1. The self-contained dwelling, in which every part of it, with its offices, is inside its own outer door. This will be most costly to construct but the management will be cheaper.

2. The associated dwelling, in which some or all of the offices are either used in common or are, at least, separate from the living rooms and approached by the common passage or corridor. In proportion to the degree in which offices are used in common will be the expense of supervision by caretakers and of work that will have to be done at the expense of the owner. The rent obtainable will be rather less.

There is great variety in the planning of each of these kinds of tenements so as to get a sufficient number of rooms from the staircase. Neither the staircase nor the passage will produce rent, and both are costly. There is also great variety in office accommodation allowed to each tenant. This has a most important bearing on questions of cheapness and of rent.

For an example of a block of self-contained dwellings, I may take those built on the Cable Street area by the London County Council. They were designed after some previous experience which the Council had had, and they fulfil all the accepted conditions of such dwellings. There is through ventilation, the closet is separated by an open lobby from the dwelling, there are small sculleries with coppers so that the family washing may be done at home. The entrances are direct from the street, but there is a through passage on the ground floor for access to the yard, which is an element of cost. As only five habitable rooms are provided on each floor to each staircase the plan, so far, is not economical; but there is not an inch of space wasted in passages inside the dwelling. The balconies are a pure luxury, but as they are much appreciated they probably contribute something towards the rent. For economy they might be left out.

Let me say here the little I have to say about external appearance. Our earliest blocks were of four storeys only and were finished with flat roofs on which clothes were to be dried and where the dwellers on the upper floors were to promenade or to play. The clothes were said to be more dirty after drying amongst the chimneys than they were before they were washed, and the tenants complained at first that they could hear footsteps on the flat down two storeys of the building. When we began building five storey blocks the plain square elevations gave dissatisfaction, so I took a good deal of pains with the Cable Street fronts, substituting mansard roofs, varying the outline, and using bricks of different colours. They cost too much, and in later designs many devices were tried in order to get a decent appearance at a moderate cost. Some variety has been obtained by the use of cheap terra cotta bricks and in other ways, and I think that quite as much money has been devoted to the elevations as can generally be afforded. A walk down Harley Street or St. James's Palace brings home to one the question why a working man's dwelling should be made

picturesque when he does not require it and will not pay for it. It is done to please the owner and the owner ought to pay for it.

Usually in a self-contained dwelling from five to six rooms, forming two tenements, are approached on each floor from each staircase. I have seen designs in which there is a staircase to four rooms, but these hardly come within the sphere of practical architecture as applied to this question. So far as I know, the only plan of self-contained dwellings in which more than six rooms are accessible on one floor from one staircase is that intended to be carried out in the block called Gainsborough Buildings, at Millbank. This contains ten rooms per staircase, and the through ventilation, if not so perfect as in some other types of plan, is, I think, practically sufficient. The weakest point is the two-roomed tenement, which, for through ventilation, depends entirely on the entrance door opening from the staircase. This is a reason for leaving all staircase openings unglazed and for putting a fanlight, made to open, over the entrance doors of the tenement. If the occupiers persist in keeping the fanlight closed they must take the consequences. I have known them get the staircase openings closed also, and I quite think it must be worse for them; but up to this date I do not know that it has told on the statistics of death or illness in the particular buildings where this has been done. I anticipate that this plan will be cheap, as the cost of the staircase, a very expensive item, is divided amongst fifty habitable rooms, whereas the cost of the staircase in all other through ventilated plans of self-contained tenements known to me is divided between only twenty or thirty rooms—a very material difference. But, on the other hand, there is some waste of room in internal passages and so the economy of this plan remains to be tested.

It will be observed that in both these self-contained plans, that is the one on Cable Street area and this one proposed at Millbank, there are rather considerable breaks in the lines of the outer walls. This cannot be so economical as a perfectly rectangular plan in which the area is well utilised for rent-producing space. Probably a plan with nearly straight elevations, and with a depth of about 28ft. from front to back, is the most economical arrangement.

In both these plans every desirable part of the dwelling is enclosed within the entrance door, for the scullery has a copper, and a wash-house would be unnecessary. If there is a public wash-house near, it is not necessary to make the scullery so large. The closets are cut off from the tenement by an open lobby. If the occupiers close up the opening by old sacks and cube sugar boxes, the results, if any, will be duly worked out by the Registrar-General. It has not been unusual in artisans' dwellings to enter the closet from the scullery, but the regulations under the Public Health Act now prohibit this arrangement, because food is, or may be, prepared in the scullery.

A third arrangement of self-contained tenements is shown in a block that is about to be erected by the London County Council at Poplar. It may be called a gallery plan, for all the tenements are approached from galleries that extend along the front of each storey. This means of access has been adopted in many places, and the idea is tempting, as the planning is most simple. The block is perfectly rectangular, and one staircase will serve a large number of dwellings. Still, the cost of the balconies must be a considerable item. Extreme sanitarians object to the obstruction of light by the projecting balcony. If you offer to enlarge the windows they say the balcony still obstructs direct sunshine; but if in the future we are all to have all our rooms fully exposed to the sun, it is a serious innovation, and I do not think the beginning can be made with houses of this class. Many persons, however, who are just able to stand the air in the street may find that in times of storm the balconies of the higher stories are too much exposed. The Corporation of Manchester has covered a large square plot with dwellings on the gallery plan surrounding an open court, and this gives a considerable amount of shelter, as the galleries

face the court. Galleries in exposed places might have their railings lined with corrugated iron, though this would obstruct the view of the street. But the value of a view of the street from upper windows may easily be exaggerated.

So far I have assumed that the site will only permit the block to be lighted in front and in rear, but there are cases where light can be got all round. Such a case is the London County Council's block in Brooke's Market, Holborn, where the self-contained dwellings are arranged with much greater facility than can usually be done. In a square block like this there need be no waste space. Some of these bedrooms are entered from sculleries, which, however, are unusually well lighted and ventilated; they might just as easily be entered from the living rooms.

Associated dwellings vary greatly in the extent to which the common use of the offices may be carried. Both the closets and the sculleries may be detached, and so placed as to be entered from a corridor. This will prevent the access of foul air from these places direct to the habitable rooms; but if occupiers are induced to keep their solid and liquid refuse too long in the rooms this advantage is only theoretical. And if the rooms, instead of having a through current of the fresh outer air, are ventilated largely from a corridor which gets the flavour of the sinks and closets, the result may be unsatisfactory. Of these flavours, that of the sink is most difficult to prevent. Our modern closets, if managed with any intelligence, ought to be free from smell.

If the closets and sinks are to be kept clean by the tenants, there must be a separate set for each tenant, the closets, at least, being kept locked. This very much reduces the economy of the associated arrangement—indeed, it is not really "associated" if the offices are still kept exclusively for the respective tenements. There are objections to the arrangement of closets in a corridor where everybody using them is under the observation of neighbours; there are objections to closets or groups of closets being too much secluded, as they become lurking-places for rough and mischievous youth; there are objections (which may find expression in reduced rental) if a tenement is approached through an avenue of closets and sinks. If the class for which we are providing dwellings is indifferent to these considerations, sensitiveness in such matters may be expected to increase.

I will take by way of illustrating the varieties of associated dwellings the different blocks erected by the London County Council on the Boundary Street area. In Sonning Buildings four tenements on each floor consisting of thirteen rooms are approached from one staircase. All closets are detached, and are grouped together near the staircase, one being allotted to each tenement. One small scullery for drawing water, but not for working, is common to the four tenements. In Taplow Buildings five tenements on each floor, consisting of thirteen rooms are approached from one staircase. In two cases the closet and scullery is included in the tenement, which is, therefore, self-contained, and in the three remaining cases the closets are approached from the corridor, one scullery sink being common to the three.

In all these cases of associated dwellings, although as many as thirteen rooms are approached from one staircase, there is a rather large proportion of passage, and in a large part of the block there is only one line of living rooms instead of two, which is uneconomical. There is some saving in cost, but on the other hand there is, as I have said, some reduction in rental value as compared with the self-contained plan.

I should be inclined to adopt as a rule the self-contained plan, each tenant being responsible for his own dwelling. But where this would be beyond the reach of the class to be provided for, I should dispense altogether with the scullery, the housework being done in the living room. In that case the water tap, with the place for dust pail, would be in the open lobby disconnecting the closet from the tenement.

If a lower class of tenement should be required it might be on the associated plan. The group of four tenements off one staircase might have two closets only, one for men and the other for women, and one draw-off tap. People of this class—I mean families earning very low wages—do not keep perishable food in the house, and do not need a ventilated larder. The amount of dust which they have to dispose of is extremely small; if they should object to carry it downstairs, a perpendicular distance of thirteen yards at the most, to a dust-bin in the yard, I should say they do not really want a new dwelling, but ought to make shift in an old one.

Mention has been made of the provision of hot water at certain times. This great convenience was first afforded by the Guinness Trust in dwellings designed by Mr. Macartney. Many other conveniences may be suggested, some of which may be made remunerative.

I think that in addition to the common dust-bin in the yard, which should always be provided, there should be closets and urinals, which would diminish the use of the men's closets upstairs. Some kind of shed or work-room might be given where the men could do little repairs for themselves, as they do in the Rowton houses. The men would probably pay a trifle for small lockers that would hold a labourer's tools; street tradesmen, in some districts, would pay for sheds just large enough to hold a barrow with their stock during the night. In the Dufferin Street dwellings, undertaken specially for costermongers, stables for donkeys were provided. In several cases the County Council has utilised a portion of a rather large back yard by making two-storey workshops, of which the tenants of dwellings have the first chance.

With regard to washing accommodation, it will pay in highly-rented dwellings, and it may be possible in cheaper buildings, to provide a small washhouse for every five tenements, which will allow of its use by each tenant one day in the week, Saturday not being a washing day. If the washhouses are amongst the dwellings the air is often full of moisture from the steam, and the smell is unpleasant. I think it best to put them in the yard or they may be put on the top of the dwellings. In the Boundary Street area the County Council has provided one large common washhouse with all modern contrivances as well as a club-room; but you cannot saddle the poorest class of tenants with the cost of such conveniences, unless perhaps where a very large number of dwellings are built.

I have thought it best to instance, both for illustration and for criticism the designs that have been carried out under my direction by the London County Council. They have been designed under conditions of extreme pressure from various quarters. The Council has had to charge only the rents ruling in the localities in which it was building, and out of the rents has had to meet all outgoings and the sinking fund for repayment of cost of buildings and land which the Treasury very needlessly, as we think, demands. They have had to be designed under hygienic conditions imposed by Government departments that are not imposed by building Acts or carried out voluntarily by those who build or live in this class of dwellings. I have pleasure in acknowledging the great skill and energy that has been brought to bear on every detail by Mr. Owen Fleming, in charge of the housing branch of the architect's department, and his colleagues.

I should like to draw attention to the great variety there is in these plans, and at the same time to say that, so far as I know, they have in every case been found highly suited to the requirements of working men's families. This may result partly from careful administration and partly from variety in the taste of the tenants, and I think it tells against a rigid adherence to any one particular plan.

One might have hoped that on any subject connected with block dwellings valuable lessons could be learned from Continental cities, where large buildings, consisting of many tenements are the rule. But after searching the chief of these cities, particularly in Germany, and consulting many books, I am surprised at the

poor results. The favourite plan just now seems to be to put blocks or rows of workmen's flats in yards behind flats of a superior class, an arrangement opposed to all our ideas. Frequently the tenement consists of a rather large room which contains all the beds, with a smaller kitchen, probably used for sleeping, with use of a closet that serves for several occupants. Lodgers are often taken who, including washing, pay a material portion of the rent. There is a system of providing a lodger's room with entrance from the staircase as well as from the tenement, and where two such rooms adjoin they might be let as a complete tenement.

I see that when we first discussed this matter on Mr. Darbyshire's paper I insisted that it was essential for these buildings to be made to pay so as to induce capitalists to invest money in them. I see every reason to repeat that view after a further experience of six-and-thirty years, and I am afraid that, owing to the increased cost of building, this becomes year by year a matter of greater difficulty. I must leave the question of cost untouched just now. I hope, however, that the discussion of this paper may bring out ideas helpful towards the solution of the housing question, which, as regards the working population of our towns, is the great question of the present day.

The Discussion.

Mr. Fellowes Prynne, in opening the discussion on the paper, said he was inclined to disagree with the statement by Mr. Blashill as to the financial basis of the workmen's dwellings schemes; with the present prices that obtained it became practically impossible to make it a profitable speculation. The state of affairs at present was a disgrace and it had become a government question, in which the State really should make an advance. Either a revolution would take place or some definite Government action must be taken in the matter. In this way the efforts of councils and other public authorities were in the right direction. Touching the subject of separate buildings (not in long blocks), they were a very great advantage where the light could be got all round.

Mr. Mervyn E. Macartney said he felt with the president that it was very important to get light all round. Too much attention could not be paid to sun and light, more almost to sun than to anything else. He would keep blocks down as low as possible. With regard to the number of persons that should be housed on a confined area he thought the usual number was about 800 persons to the acre in most of these blocks. He preferred the staircase excluded from the inside but not exposed to the external air. As a rule the staircase was an extra living room or playground for the children, and if it was entirely exposed it would not be a very suitable place for them. He therefore thought an internal staircase with a good-sized well-hole and a door at the bottom which was not entirely closed, that was to say, which could be put up on necessity, was the best method.

Mr. Owen Fleming said he had gone down and lived for the last five years in model dwellings in Stepney and had experienced the many objections to them. There were the many distressed happenings every day in a crowded community; there was child birth and death; and when the whole family was crowded into a couple of rooms there was no interest in life. It was almost impossible to live under the circumstances. But what was to be done? There were men earning a wage not sufficient to live with; and therefore the best must be given for their money. This money had to be considered very, very carefully. Take, for instance, such a point as distance between party walls; if these were less than 30ft. apart, the other walls could be made 14in. less than under the Act. He thought this was one of the reasons why in the first plans the architects came out on the wrong side. With regard to the overcrowding in model dwellings, the London County Council had carried out two great schemes at the Boundary Street area and on the Millbank area,

at which latter they had had to provide for over 8,000 persons on roughly about forty acres. If anyone would take the trouble to go down to the Boundary Street area and stand in the central area and look around and down the radiating approaches he did not think it would occur to him as being overcrowded. He thought that viewed in the same way it would be considered that the architect had been very extravagant with his space on the Millbank area. With regard to staircases, the children did not, as far as he knew, play on them, but in the yard. There was the advantage in having an open well staircase outside the building that the smells from lower floors did not become oppressive on a hot day. He had found the architectural appearance of these buildings was appreciated by their inmates, and he was convinced of the advantage of giving some attention to their external appearance, but whatever views might be held about this point they had got to make it pay, and unless it were made to pay the design failed.

Mr. Charles Joseph thought the question as to the number of persons on the acre did not seem to be of the highest moment as long as too many were not crowded upon the floor area. The cost seemed to depend upon the way the buildings were planned; angles were a great expense, whereas building square could be done with great cheapness. Also the walls should come close to each other to avoid making them thick. Under the old Building Act six-storey buildings could be erected with only 14in. walls, whereas under the new Act they had to be built 18in., but yet the buildings erected under the old Act had not fallen down. As far as he had been able to discover there was no higher death-rate in back to back tenements than in others, and these had the advantage of avoiding external walls, which were costly.

Mr. W. H. Seth-Smith, in proposing a vote of thanks to Mr. Blashill, said the great question of finance was a burning one which would have to be settled somehow, either by running up the buildings higher and reducing the cost of the ground rents, or by Government subsidising them. He shared the views of those who deprecated the limiting of the number of persons to the area, as with the steady improvement in sanitation there was not the same necessity as formerly. Mr. F. G. F. Hooper then seconded the motion, and Mr. H. W. Pratt and Mr. F. W. Lane supported it.

Mr. C. H. Brodie said his experience was that it was very rare for a closet to be found inside the dwellings used by the lower classes, and that as they were thus used to going outside he saw no reason why they should be placed inside where they were a constant nuisance. In Vienna he was told it was quite a common occurrence for several fine suites of rooms to be on the first floor, with a separate entrance, and he thought if this were done in this country it would help to reduce the rents for the poorer apartments. Shops could be placed below in the same way wherever possible. It was a mistake to take simply the area within the boundary of the site to compare it with the number of people on it. The area really should include half the surrounding roads and open spaces. In the case at Millbank, part of the river and a portion of Battersea Park ought to be included in the area.

The vote of thanks was then carried by acclamation, and Mr. Blashill, in reply, said the London County Council had not rehoused upon the lines on which they had been compelled to go; they had taken in a different class of persons. A little higher rents were received from the top floors in some cases where persons preferred to be at the top. In the earlier tenements the walls were not plastered, but simply painted with two or three coats. A good plan was to keep the paper, when such was used on the walls, about half an inch from the top, by which means vermin could be prevented from finding a lodgment there. Mr. Brodie had mentioned the system of having two sets of rooms in Vienna; this also obtained in Paris; another method of cheapening the rents was to put the general dwellings behind the workmen's dwellings.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Metrical System and Building.

GRAVESEND.—G. B. L. writes:—"I should be glad if you could give me some particulars of the metrical system and its application to architecture, building plans, surveys, and accounts."

In this country the metrical system is not applied to the purposes referred to. A comparison of this system with the Imperial system is, however, given in Whitaker's Almanack, and could, no doubt, be found also in any standard table book.

HENRY ADAMS.

Prison Cell Doors and Windows.

GLASGOW.—W. E. S. writes:—"I should feel obliged if you could give me the names of some firms who supply prison cell windows, doors, and other fittings. I have the new catalogue of Mr. James Gibbons, St. John's Works, Wolverhampton, but, though he supplies cell doors, cell windows are not included in his list."

Messrs. Rudge and Griffiths, The Foundry, Stafford, are makers of air grids, windows, and fanlights for prisons. Prison cell doors are made by Messrs. E. Cotterill and Co., 36, Ludgate Hill, Birmingham. In ordering doors it should be stated if a ration trap is required.

G. H. J.

Civil Service Appointments.

WANDSWORTH COMMON, S.W.—G. H. C. writes: (This reply also relates to the query of E. O., Chelsea):—"Can you inform me where I can get particulars concerning appointments under the government suitable to myself? I was articled to an architect and have spent about seven years and a half in the profession in offices and on works, and have gained several good certificates in subjects connected with the profession."

The appointments under the government for which an architect would be eligible are:—Assistant Civil Engineer under the Admiralty; Assistant Surveyor, Royal Engineer Civil Staff; Assistant Surveyor in the Office of Works; Assistant Surveyor in the Director of Works Department, Admiralty. Particulars of all these appointments, and the subjects of examination, can be obtained free of charge from the Secretary, Civil Service Commission, London, S.W.

HENRY ADAMS.

Cleaning a Stone Altar and Reredos.

HEREFORD.—R. A. D. writes:—"How can I remove stains and splashes from a Caen stone altar and reredos without scratching the surface?"

To clean a reredos and an altar of Caen stone a capable soft-stone mason should be employed. Fine glass-paper, wrapped around pieces of wood of the reverse section of the mouldings, could be used to clean the stone. Great care must be taken to avoid destroying the arisies. Do not, on any account, attempt to glass-paper any carving. To clean the carving, if there is any, spirits of salts in clear water should be used, with a rather stiff hair brush—about half-a-pint of acid to a pail of water. If much difficulty is experienced in removing the splashes, use plaster of Paris mixed with potash. This should be laid on the spots only, and allowed to remain several hours. Thoroughly brush off all dry dust before using any water. Finish by washing the whole surface of the stone with clean water.

G. H. J.

Mitering Machines.

BIRMINGHAM.—REGULAR writes:—"Which is the best kind of mitre machine for picture framing?"

For small work, the mitre cutter known as Booth's, which, or a modification of which, can be had at any large tool shop, to cut up to 2 in. mouldings, for about 12s., or of double this capacity for about a guinea. For larger work, Shute's mitre cutter (F. W. Reynolds and Co., Blackfriar's Road, London, S.E.), to cut up to 5½ in., at £2 15s., or to 7 in. at £6 10s., would be found a reliable tool. But the very best tool for these (and other) purposes, which will shave square as well as mitre cuts, is a machine which was exhibited at the late Building Trades' Exhibition by the S. A. Woods Machine Co., of Boston, Mass., U.S.A. Particulars of this tool can be obtained from the English representative of the company, Mr. J. Roberts, care of Arthur Waring and Co., Ltd., Warrington.

H. E.

Reducing Brickwork.

F. A. writes:—"What is the best method, in abstracting, of reducing brickwork of any thickness to 1½ or 1 brick?"

Brickwork is abstracted under two columns, 1½ B and 1 B. In entering walls of thicknesses other than 1½ and 1 B, the required amount is made up under the two columns. For example in a two-brick wall twice the amount is entered under the one-brick. In a 2½ B wall, the entry is made once under each. In this manner walls of any thickness may be abstracted. To reduce to rods the two columns are totalled. From the total of the 1 B column one-third is deducted, giving an equivalent amount of 1½ B. This amount is added to the total under 1½ B, and the result divided by 272 to give rods.

HENRY ADAMS.

Roof for Billiard Room.

GRAVESEND.—VESWOR writes:—"Can you give me a sketch of a suitable truss for the roof of a billiard room? It is to span about 25 ft. The room of course is to be top lighted and there must not be any prominent tie-beams to cast a shadow across the billiard table. I should also be pleased to have any suggestions regarding the designing of a first-class billiard room."

A suitable truss for the roof of a billiard room would be a queen-post truss, as shown in the accompanying illustration. A lantern light

DESIGN FOR BILLIARD-ROOM ROOF. BY HENRY ADAMS.

is built in between the trusses, which are arranged so as not to come over the table. The design of a billiard room depends upon circumstances, the nature of the establishment to which it is attached, public or private, the amount to be spent upon it, &c.

HENRY ADAMS.

Fixing Glass in Stonework.

LONDON, S.W.—W. E. writes:—"How is plate-glass secured to the stone mullions and transom of a window, without wood sashes?"

A section through a window showing head, transom and sill would be of service; also, particulars as to how the glass is put into the grooves."

Various methods have been tried for securing glass in stonework, but the method usually adopted is to build a light angle iron frame, with an adjustable fillet, into rebates formed in the stonework, illustrations of which can

FIXING GLASS IN STONWORK.

be found in any manufacturer's catalogue. Another method, dispensing with the introduction of a frame, would be to bed the glass itself into the stone rebates and secure it in position by means of iron or hardwood fillets screwed to wood plugs, as shown in the accompanying illustration.

HENRY ADAMS.

Council's Power to Appropriate Land.

HANDSWORTH.—AN ARCHITECT writes:—"The legal notes in your excellent journal for January 31st are not only interesting but useful to architects. It is well to have a clear idea as to the powers of the surveyor as servant of an Urban District Council when dealing with building plans. I have a letter stating that certain plans of mine will not be passed by an Urban District Council until about 100 yds. of my land are given up to the Council to widen a lane. They offer no compensation for the land, which is the boundary of an ancient and well-defined bridle-path leading to the parish church. Have the Council the power to take land in this manner?"

The surveyor of an Urban District Council

has no "powers" when dealing with the plans of an architect for building. He has duties towards his employers and the public, whose servant he is. Whatever powers exist in reference to such matters are vested, not in the surveyor, but in the Council. These powers are limited by law, and, it is hardly necessary to say, do not entitle them to take compulsorily any man's property without making compensation. The Council cannot make their approval of our correspondent's plans conditional upon the surrender of any property to them. If the plans are not in con-

travention of any valid by-law, the Council are bound to approve of them, and can be compelled to do so by *mandamus*. If they are in contravention of such by-law, the Council cannot effectually approve of them.

H. P. B.

How to Value Houses and Land.

SUBSCRIBER writes:—"Will you please state fully how to value houses and land? Do you deduct property tax and income tax in addition to insurance and any other local taxes, and is 16½ years' purchase generally a good basis to accept?"

The valuation of house property differs materially from that of land. The value of a house depends upon its class, position, state of repair, &c., and it will command a widely differing number of years' purchase accordingly, ranging usually from 16½rds. to twenty-five years in medium localities. The value of land depends upon whether it is (1) only of agricultural value, (2) of accommodation value, (3) of building value; commanding in the first case perhaps 3 per cent., or 33½ years' purchase of the net annual value, in the second 4 per cent., and in the third 4 to 5 per cent. Therefore, it is impossible to give as a basis a set number of years' purchase. It is not usual to deduct property tax or Schedule A income tax, for the reason that all kinds of property, landed or otherwise, are chargeable; but all other taxes paid by the owner, in addition to repairs, insurance, land tax (if unredeemed), tithe, water rate, &c., and ground, &c., rent, if a leasehold property, must be deducted. Take the following example: A leasehold house, rent £100 per annum, term forty-five years, ground rent £14, with 125 acres of freehold land, five acres of which are near a town, let for football ground at £2, the remainder at £1 per acre.

(1) HOUSE.			
Gross Annual Rent	£100		
Deduct—Repairs 5%...	5 0 0		
Insurance 1½% on cost	1 0 0		
Rates, taxes, &c.....	5 0 0		
Collection and management 2½%	2 10 0		
Empties and bad debts 2½%	2 10 0		
Ground rent.....	14 0 0		
		£30	
Net annual income		£70	
7% for 45 years=13'6 years' purchase		13 6	
Value of Leasehold.....	952 0		£952 0 0
(2) LAND.			
120 acres at £1.....		£120	
Repairs, tithe, taxes, and management		20	
		£100	
Years' purchase	30		£3,000 0 0
5 acres at £2		£10	
Deduct repairs (nil), rates, and taxes		1	
		49	
Years' purchase at 4%.....	25		£225 0 0
Total value			£4,177 0 0

E. BRAND, P.A.S.I.

Rates and Rating.

GRAYS.—R. W. writes:—"Is there any method of enforcing, from the Assessment Committee of a Rural District Council, a deduction of one-fourth, when the gross rental is under £20, beyond the expensive process of an appeal to Quarter Sessions? What ought to be the rateable value of tenements let at 6s. per week, in a district where the rates equal 8s. in the £, and the water rate 7½ per cent.?"

No, I am not aware that you can enforce any specific deduction from an Assessment Committee, as they are supposed to exercise their judgment as to a sufficient deduction for each particular case. If you dispute this judgment the only way is to appeal, and a notice of your intentions will of itself often bring about a readjustment of affairs, if the Committee plainly have a feeble defence. The rateable value of the said tenements might be as follows, although without knowing the real

facts of the case it is only possible to approximate:—	£ s. d.
Annual rent at 6s. per week...	15 12 0
Deduct—Rates=8s. in £1 £ s. d.	
on £11 (rateable) 4 8 0	
Water rate, say ...	0 16 6
Repairs, 10 per cent. 1 11 0	
Insurance, say ...	0 3 0
	6 18 6

Rateable value ... 8 13 6

E. BRAND, P.A.S.I.

Views and Reviews.

THE YEAR'S ART.

The twenty-first annual issue of this excellent reference book has just come to hand. This work is now recognised to be the most complete and standard work of its kind. With this number a series of portraits has been included of some of the more important workers in the field of Decorative Art. As the able editor, Mr. A. C. R. Carter, points out, the book has wisely not been confined for some years past simply to a record of the progress in Pictorial Art; and the Arts and Crafts Society has afforded an opportunity of showing this wider interest in the decorative arts. Mr. Edward F. Strange contributes an article on this revival under the heading "Applied Art." The volume is most handy for reference and contains information of almost every art museum, exhibition or society. Most interesting reading is always to be found in the section devoted to the Artists' Sales at the Royal Academy and New Gallery, and the Art Sales of the past year. A leading feature is made of the list of artists with their addresses and an indication of the galleries at which their work was exhibited during 1899. The very complete index enhances the value of the work immeasurably.

"The Year's Art, 1899." Compiled by A. C. R. Carter. London: Virtue and Company, Limited, 25, Ivy Lane, Paternoster Row. 3s. 6d.

ART AND THE POETS.

We so seldom nowadays see steel engravings used as book illustrations that we feel grateful to Messrs. Virtue and Co. for having re-issued in a cheap form this very charming collection of engravings and excerpts from the poets. The engravings are from pictures by Turner, Martin, Stothard, Roberts, and other British artists, some of whom were better known a generation ago than they are to day; although the illustrations are by no means of equal merit the best of them are extremely beautiful and afford a welcome relief from the ubiquitous process block. One can well believe that the compilation of this book was a delightful task for the editor, Mr. Robert Bell; his aim has been to bring together some of the choicest works of British poets, painters, and engravers. With such an aim it was scarcely possible to produce a dull or unattractive volume. But as the editor rightly says in his introduction, "the best materials may be marred in the preparation," and we are bound to say that to a certain extent that is just what has happened in the present instance. For example, what a strange and indefensible use is made on page 168 of that noble passage in Milton's "Comus" which begins:

"So dear to Heaven is saintly chastity,
That when a soul is found sincerely so,
A thousand liveried angels lackey her,
Driving far off each thing of sin and guilt."

Our anthologist has actually begun his quotation at the third of these lines; that is to say in the middle of a sentence, with the object—apparently—of so perverting the sense of the original that the lines may the more fittingly accompany a picture of angels watching over a sleeping child. This strikes us as sheer barbarism. Very little better is the way in which a passage from Spenser's "Faery Queen" has been quoted (on page 112). The two concluding lines of one stanza are followed, without any break, by the whole of the next stanza, thus effectually disguising the perfection of poetic form which belongs

to the Spenserian stanza; it would have been much better to quote the whole of both stanzas, leaving a proper break between them.

As regards the choice of poetic extracts, we are not disposed to be over critical; if to our thinking the editor has admitted much that is mediocre to the exclusion of many passages of infinitely higher quality, we have to admit that the making of anthologies is essentially a matter in which—if such a very unpoetical expression may be allowed in this connection—one man's meat is another man's poison. The only completely satisfactory anthology is that which every man makes for himself. Notwithstanding its defects, however, the book is emphatically one to be purchased and taken care of. It has been most attractively produced, and, in view of the decay of steel engraving, the opportunity of obtaining such a collection of excellent examples of an almost extinct art is not likely soon to recur.

"Art and Song." Edited by Robert Bell. London: H. Virtue and Co., Limited, Ivy Lane, Paternoster Row, E.C. Price 6s. net.

LOCAL GOVERNMENT ANNUAL.

The ninth issue of this useful little work contains many new features, including the charges for water and gas levied by the London companies; the population of the provincial unions; a complete list of all the parks and open spaces of London, with the authorities controlling them; abstracts of the fourteen Acts of Parliament affecting local government which were passed last session, and some seventy pages of short articles and paragraphs under eighteen heads, dealing with every branch of local government. This section is called "The Local Government Companion." In it we find some sixty "mems. for members and officials"; points about parish council law; how to obtain charters of incorporation and what they cost; information respecting the growth and cost of electric traction; the housing question, and where and how it is being solved; the legal decisions of the year affecting local government; the principal adoptive Acts; the laws of continental countries in regard to tuberculosis; facts about the local Government Board and its work; figures bearing upon municipal rating and finance; and many other interesting facts. The directory portion contains the names of the chief officials of every public body in England and Wales, including every department of public work, whether ordinary or special. The facts are most pithily put and so clearly arranged that any point upon which information may be required can easily be looked up in a few minutes in business hours. The handbook is not a large one, but that is not saying it is not comprehensive. Much could be added but without any particular advantages.

"The Local Government Annual and Official Directory, 1900." Edited by S. Edgecumbe-Rogers. London: "The Local Government Journal" Office, 2, Dorset Street, Fleet Street, E.C. 2s. 6d.

A HANDBOOK TO THE STUDY OF POMPEII.

It is most probable that in the future the study of Pompeii will be taken up more thoroughly by the architectural student than it has been, and already the need has been felt for a comprehensive handbook providing an introduction to the study of the remains of this town. To say that this need has been supplied by Mr. Mau and Mr. Kelsey would not be doing them full justice; for not only does the book serve the purpose of a handbook and guide, but it will be found most interesting and useful to the general reader who may never have the chance of visiting the site of this ancient Campanian town. Pompeii, of course, has always had a great fascination for the archaeologists, by whom it has been largely visited; but however interesting archaeology may be, it is only useful to the present day so far as it investigates the knowledge of the ancients and gives it to us as an aid to our art and science. From this point of view Pompeii must rank very high; it, as no other source outside the classical authors, helps us to understand the ancient world. The town was not a great one or more remarkable than its neighbours, but from this very

reason it is representative of every-day life at the time of its overwhelming, which, coming in the way it did, has preserved the surroundings of life as a whole, with all the humblest details intact. Being thus typical of the ordinary life of the time, Pompeii does not show us the noblest creations of ancient art, for these, as is most natural, are only to be found in the great centres of wealth and population, where genius would find material encouragement. It need not be feared that, as this book is interesting to the general reader, it will deal inadequately with the matters of interest to the architectural reader; the book does full justice to the architecture. Architecture need not become wearisome to lay-readers if properly treated, and although the architectural portion of the text considerably outweighs the others, the interest hardly flags for a moment. The work is a free translation from the German of Professor Mau, of the German Archaeological Institute in Rome. The work of translation has been excellently done by Mr. Kelsey, an American. In several chapters the German manuscript has been abridged, while in others slight additions have been made. The volume is well and fully illustrated, printed on good paper, and handsomely bound.

It is strange how the impression has got about that the overwhelming of Pompeii in 79 A.D. was by molten lava. The fact is that a violent eruption of Vesuvius hurled to a great height the accumulation of volcanic ash and pumice-stone that had been heaped up on the mountain by former eruptions, these coming down again upon the surrounding country. On the west side of the mountain the debris mingled with torrents of rain and flowed as a vast stream of mud down over Herculaneum; but on the south side it spread out into a thick cloud, which covered Pompeii and the plain of the Sarno. Out of this cloud first broken fragments of pumice-stone about the size of walnuts rained down to the depth of 8ft. to 10ft.; then followed volcanic ash, wetted as it fell by a downpour of rain, to the depth of 6ft. or 7ft. At Pompeii only the roofs of the houses, where these had not fallen in, projected above the surface. Although masses of flowing slag fell with the pumice-stone there cannot have been much heat, as cavities have been discovered which human forms originally occupied, showing that the bodies must have remained undecomposed long enough to allow the ashes to harden around them.

The first excavations were undertaken by the survivors shortly after the destruction of the city. It is seldom that a house is found undisturbed, and little household furniture of value has been found. Not only was furniture removed, but the excavators carried away valuable building materials as well, as in the case of the buildings about the Forum, which were almost completely stripped of their marble. The present excavations have been carried on in a most able manner, and up to the present time about one-half of Pompeii has been uncovered; but it is to be regretted that many articles of furniture and objects of art that could be easily moved have been taken to the Museum at Naples. Of course, the keeping of small sculptures in the exact positions in which they were found, as has been done in the case of some houses, necessitates extra expense in maintaining the houses locked and guarded; but it is well worth it. The most regrettable thing that has occurred in this respect has, perhaps, been in the treatment of paintings. Generally the best pictures have been cut from the walls and transferred to the Museum, while the decorative framework has been left undisturbed. In this way the effect of the decorative system as a whole has been destroyed, for the picture forms the centre of a carefully elaborated scheme of decoration which needs to be viewed as an artistic whole in order to be fully appreciated. When we consider that Pompeii probably provides the finest specimens of decorative methods of wall painting, we can appreciate the great advantage of keeping these walls intact, as is happily now being done.

Six centuries lie between the dates of the earliest and latest buildings at Pompeii, and

the architectural history of the city falls naturally into six periods, according to the styles of construction. Exclusive of wood, the principal building materials were Sarno limestone, two kinds of tufa (grey and yellow), lava, a variety of limestone wrongly called travertine, marble and brick. Bricks were used only for the corners of buildings, for doorposts, and in a few instances for columns, and occur simply as a facing for rubble-work. The bricks are generally less than lin. thick, shaped like a right-angled triangle, and were so laid that the side representing the hypotenuse—about 6in. long—appears in the surface of the wall. The styles of masonry are characteristic, and may be distinguished as masonry with limestone framework, rubble-work, reticulate work, quasi-reticulate work, ashlar work, and, in the case of columns and entablatures, massive construction. The third period of Pompeian architecture, known as the Tufa period, on account of the favourite building material having been grey tufa, was of a decidedly high artistic character. This period coincides with the first style of wall decoration—the Incrustation Style—which aimed at imitating in stucco the appearance of a wall veneered with coloured marble. The second style of wall decoration is known as the Architectural style, for in part, as the first style, it imitated a veneering of marble, not, however, with the help of slabs or panels modelled in stucco, but by the use of colour only, laid on walls finished to a plane surface; in part it made use of architectural designs, which were painted either correctly or with at least some regard for proper proportions. This style gave place to a third, or Ornate Style, which is characterised by a freer use of ornament, and the introduction of designs and scenes suggestive of an Egyptian origin. The fourth, or Intricate Style, represents, with its involved and fantastic designs, the last stage in the development of Pompeian wall decoration. At Pompeii we see accomplished in less than two centuries a complete revolution in matters of taste relating to architecture. An entirely new feeling had been developed. A beauty of contour and of symmetrical proportion found in Greek architecture had no charm for the Pompeian of the later time; its place had been usurped by a different form of beauty, that produced by the use of a variety of brilliant colours in association with forms that were intricate and often grotesque. The study of Pompeian houses is most important, for the chief sources of our information regarding the domestic architecture of ancient Italy are these remains and the treatise of Vitruvius. The Pompeian houses present many variations from the plan described by the Roman architect; yet in essential particulars there is no disagreement, and it is not difficult to form a clear conception of their arrangements.

A word must be said in praise of the useful restorations illustrated in the book. The drawings are not fanciful, but have been made with the help of careful measurements and of computations based upon the existing remains.

"Pompeii: Its Life and Art." By August Mau; translated by Francis W. Kelsey. London: Macmillan and Co., Ltd. 25s.

Heavy Failure in the Leicester Building Trade.—The Official Receiver of the Leicester Bankruptcy Court has issued a statement of affairs under the bankruptcy of George Tuffley, of Earl Howe Street, Leicester, builder. The summary shows unsecured liabilities of £11,032, and assets £632, leaving a deficiency of £10,400.

Winning Ore from the Sea.—The Hodborrow Iron Ore Company, Milloom, Cumberland, will shortly commence work upon the new sea wall that the company has in view for the purposes of winning the hematite iron ore that is lying seawards (under the tide at high-water mark) of their present sea wall, built some fourteen years ago. The new wall will reclaim about 170 acres of land from the sea, and will be 6,750ft. in length. The cost is stated to be about £220,000. Deposits giving 13ft., 24ft., 36ft., 49ft., 58ft., 70ft., 90ft., 98ft., and 102ft. of solid ore have been proved.

GAS ENGINEERING.

IN reviewing the progress made in the generation and supply of gas, the president of the Society of Engineers, Mr. Henry O'Connor, in his recent inaugural address, said that where a sufficiently large quantity of coal was required, the most efficient plan of transporting it to the retort house was by overhead railways and special self-emptying trucks. The simplifying of regenerative furnaces was advocated, and allusion was made to the saving of fuel by this system of firing and by the thorough knowledge of its principles. Some observations on sloping retorts, with their advantages and disadvantages, led to the description of stoking machinery and a simple and cleanly arrangement of shower baths for stokers was described, the same being intended to take the place of the usual plunge baths, which so rapidly become fouled. Mention was made of the advantages of coke as fuel, on account of the large percentage of carbon in it, and the great increase in the use of coke breeze was incidentally referred to. Some remarks followed upon the recovery of cyanogen from the gas, and on the different methods generally adopted for its removal in the forms of ferrocyanide of potash or soda and sulpho-cyanide. Weldon mud and precipitated oxide of iron, which are by-products of other manufactories, formed admirable substitutes for bog ore in the purification of gas from sulphuretted hydrogen, more especially with the use of oxygen, made by the Brin process, for their revivification *in situ*. There was great need of early and systematic planning in connection with successive extensions of a gas works. With regard to gas engines, the president observed that they were not sufficiently pushed by gas engineers, as they did not use them to the full extent possible in their own works, and could not, therefore, expect others to employ them for the many purposes for which they are so admirably adapted. The large size of some of the gas engines made on the Continent enabled them to be used very economically for the supply of power. A description was given of a novel internal combustion engine invented by Mr. P. F. Macallum, which had given very admirable results when tried experimentally on a small scale, and which it was predicted by experts would be capable of providing 1 h.p. per hour with only $\frac{1}{2}$ lb. of coal. Strikes among the gas workers and the cost to the various gas companies had led to the introduction of carburetted water-gas, which had now proved so useful in this country that plant for nearly 100,000,000 cubic ft. per day had been erected. The president agreed with the opinion that it was not to be feared that there would be more accidents owing to its introduction than with ordinary coal gas. The undoubted great advantages of the system and the simple nature of the process were commented on. Acetylene, which was at first thought likely to prove a rival to coal gas, had been only found useful for country houses beyond reach of mains. With regard to the Welsbach incandescent burner, a stronger mantle was advocated. This led to an allusion to the need of greater knowledge of gas matters on the part of the ordinary gasfitter, and to the suggestion that lectures should be given by gas managers and others upon the points to be most carefully borne in mind by the gasfitter and the general public.

The Dublin Master Builders' Association held its annual dinner last week, when the president, Alderman the Right Hon. Joseph M. Meade, occupied the chair. About 120 gentlemen were present.

Cartwright Memorial Hall, Bradford.—The Cartwright Memorial Hall Committee of the Bradford Corporation have agreed to allow contractors to tender for the whole, or any particular part, of the work in connection with the erection of the Cartwright Memorial Hall. Originally, tenders had to be for the whole of the work, which caused much dissatisfaction.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"Beauty is truth; truth beauty."—KEATS.

The Ruskin Union.

THURSDAY last being the eighty-first anniversary of Mr. Ruskin's birthday, a meeting was held at St. Martin's Town Hall for the purpose of forming a Ruskin Union. The President, Mr. Frederic Harrison, supported the proposal to found such a union. Very few had really studied Ruskin's writings, and those who had entertained various ideas with regard to his work and character. A Union for the purpose of studying his works would, therefore, seem to be a most desirable thing. No single writer exceeded Ruskin in mere bulk of work, and perhaps no English writer even approached him in the encyclopædic character of his work. Mr. Mark Judge proposed "That a Ruskin Union be now formed." Meetings would be held for reading and discussion, and a journal of proceedings would be published. The subscription would be half-a-guinea annually, and the management would be vested in an elected council. The Rev. J. P. Fauntorpe, president of the Ruskin Society, and principal of Whiteland's College, seconded the motion, which was carried unanimously.

Some Light on Art in Austria.

IT is a common but an erroneous belief that Austria is a country in which the cultivation of art in its various forms receives special attention, and in which the artistic faculties of the people are far more highly developed than in most other countries, Great Britain in particular. The Austrian is often described as a man of essentially artistic tastes, who is born with a keen appreciation of things artistic which is quite foreign to the prosaic Englishman. There is, however (says the "Morning Post"), little justification for this estimate of the ordinary Austrian. Though Vienna has acquired considerable importance as an art centre, yet the diffusion of artistic culture in Austria is not greater than, if it is as great as, it is in England, while the Austrian Government is remarkably lax in encouraging the promotion of art and the spread of artistic education. It is stated, in fact, that Saxony is the only country in Europe where there is less State aid to the cultivation and diffusion of art than in Austria. There are only three art schools in the whole of Austria which are supported by the State. The most important of these is the Academie der Bildenden Künstler in Vienna, the headquarters of which are in the magnificent pile of buildings on the Schillerplatz. The Union of "Secessionist" Artists is an offspring of the Genossenschaft der Bildenden Künstler, which works on somewhat similar lines. The "Secessionists," or Impressionists, were dissatisfied with the prominence given to classics to the exclusion of modern art by the parent society, and they seceded to form their own organisation and open their own gallery. The Impressionists' Gallery, viewed simply as a specimen of architecture, is one of the sights of Vienna.

The Working Man and Art.

THE "Secessionists" have set an excellent example by arranging with trade unions and other labour organisations for the visit of working-men to their gallery on Sundays. The workmen are admitted in groups of twenty for the sum of twopence, and a guide is provided who explains to them in simple language the meaning of the paintings and works of art. Similar advantages are conferred by the "Secessionists" on students of all faculties from any Austrian university. But though the public enjoys every opportunity of studying the works of art exhibited in the various galleries of Vienna, comparatively little use is made of it. It is stated on good authority that 80 per cent. of the population of Vienna has never entered an art gallery, and it is certain that the majority of the visitors to

the Viennese art exhibitions are foreigners. Only a very small number of provincial towns possess art museums, and such as exist are badly maintained and poorly visited. The Emperor Francis Joseph is the greatest patron of art in Austria, if not in Europe, but, with the exception of Prince John II. of Liechtenstein, the Austrian nobility does little for the fostering of art. Considerable attention has been paid in Austria to the application of art to industry. The first step in this direction was taken by the architect Entenberger, who in 1867 founded the institution now known as the Austrian Museum of Art and Industry. The object of this institution is to train industrial manual workers, and to promote by exhibitions the appreciation of artistic handiwork among the general public. The British Consul-General in Vienna, Von Schoeller, has been foremost in promoting the excellent work done by the Museum of Art and Industry. From the foregoing it will be seen that the current impression of Austria as a great art country, and the Austrian as a zealous student of art, is entirely wrong. We, however, remember how critics, writing from Vienna, like to point out the great lack of appreciation of art exhibited by the Britisher, as if such a thing were unknown in his own country. The scriptural parable about the "mote" might well be taken to heart by the aforesaid critics.

A Doomed Church.

THE extension of the already great terminus of the London and South-Western Railway at Waterloo, recently decided upon, will clear away a portion of Charlotte Street, Lambeth,

ALL SAINT'S CHURCH, LAMBETH. DRAWN BY CHARLES G. HARPER.

a street more familiarly known as the "New Cut." With the houses and the by-streets to be demolished, the church and the entire parish of All Saints will disappear and pass out of existence. Never before has a whole parish been wiped out for railway purposes. The church is one that need not be regretted. It is only some fifty years old, built of common brick in a style fondly supposed to be Norman, and now in an exceedingly dilapidated and woe-begone condition. We give an illustration of it above.

Felu, the Armless Painter.

CHARLES FRANÇOIS FELU, who died last week, was a striking example of what a man may do even without arms. He was born in 1830 at Waarmaede, near Courtrai, North Flanders, and began to study painting at Antwerp when already twenty-five years old. By means of his feet he copied some hundreds of the best masterpieces to be found all over the world, especially in America. When painting, M. Felu leaned slightly backwards, to enable him to raise his foot to the level of the canvas. He opened the paint-box and mixed his colours without difficulty, and worked quite easily. Holding the palette by the left great toe, passed through the orifice

like a thumb, with the other foot he manipulated the brush with astonishing skill and confidence. At meals he used a knife and fork, and managed his own drinking glass. Until the last few years he always shaved himself, and never had an accident. His one grievance was that he could not gain mastery over a button-hole.

William Ridgway: Artist Engraver.

AT the Highgate Cemetery, N., last week the body of Mr. William Ridgway, once a well-known artist line engraver, was buried. Amongst the more famous works that he engraved were Holman Hunt's "Light of the World" (1854), now in Keble College, Oxford; "Christ Borne to the Tomb," by Gustave Doré; and "A Visit to Æsculapius," by the President of the Royal Academy, Sir E. J. Poynter. The last-named picture was bought for the Chantry Bequest, and the engraving made from it by William Ridgway was a splendid specimen of the fine work in which he excelled. The art of steel-engraving is fast dying out, chiefly owing to the long time it takes to execute a single picture—sometimes as much as two or three years. It is no wonder, then, that artists of the younger school, of whom Mr. Joseph Fratt, the engraver of Rosa Bonheur's pictures, is a conspicuous example, turn their attention to process work. It is more speedy, and—it pays. Mr. Ridgway was nearly eighty years of age, and for some years past, and up to a few months of his death, gained his living by engraving banknotes, cheques, &c., for a firm of city printers.

Contractors' Cranes.

THE necessity for greater care to be exercised in connection with the cranes that are used for hoisting building materials was emphasised just a week ago by the deplorable accident that occurred at Leeds. For several months past the Leeds Estate Company have been carrying on building operations in connection with a huge block of property facing Briggate and the new street on the north side of the Empire Palace. To assist in these operations a crane was placed near the hoarding which faces Briggate, and on Wednesday last it was in use for the purpose of lifting iron girders, which had been deposited in the roadway, on to the site of the new buildings. The crane, which weighs about five tons, was in the act of raising four girders, weighing together about fifteen hundredweight, when the cogs of the jib wheel broke, releasing the jib and causing the girders to fall with a crash on to the pavement. As is usual about this time of the day, many persons were passing by, and one, a lad of fourteen named Percy Clarke, was caught by the falling iron and instantly killed. A labourer and a little girl were also knocked down and severely injured. Several narrow escapes were reported, and it was surprising that much further mischief was not done, seeing that the girders were swung almost into the centre of the thoroughfare. Some time before the breakdown happened the crane had been employed in lifting granite pillars weighing considerably over three tons, and the strain upon the cogs must have been enormous. It is not right that cranes of this kind, which are used constantly throughout the day, should be allowed to overhang the road or pavement, and we hope that steps will be taken to prevent the occurrence of such accidents as that referred to above.

Manchester's New Statue.

THE statue of Her Majesty the Queen which Mr. Onslow Ford, the eminent sculptor, is at present executing for the Manchester Corporation will be double life-size and will represent our sovereign seated on her throne, with her head surmounted by a coronet, her sceptre in her right hand, and the orb in her left. She is wearing her garter robes, with the sash and star of the order on her breast. Under the coronet a handsome veil is draped; in order that these might be copied with scrupulous care, she lent it to the sculptor for a lengthy period. The statue, from its base to the top of the coronet,

is 9½ ft. in height. The height of the chair of state will be 19 ft., and the pedestal 5 ft. This will be reached by half-a-dozen 6 in. steps. The massive chair will be sculptured in marzani marble. In a division between the mouldings at the top of the back of the chair St. George and the Dragon will appear, and just above her Majesty's head the Royal Arms will be engraved. To avoid having a large blank space at the back, Mr. Ford has designed and executed a model of an allegorical figure of "Maternity." This comprises a partially draped female figure with a young naked baby in each arm. The figure will be sheltered in a niche behind the statue, and will give an added beauty to the completed work. Over its head the arms of the Manchester Corporation, with the shield supported by an heraldic antelope and lion guarding and the motto "Concilio et labore," appears. The monument will be seen at its best from the opposite side of the street. The figures of the Queen and Maternity, being in bronze, will be practically indestructible. The statue, according to present arrangements, will be unveiled in October next. As some idea of the time which some works of similar magnitude have taken to complete, it may be mentioned that Stephens' great monument of Wellington, which was placed in St. Paul's Cathedral, took the sculptor twenty-two years, and he died before the work was finished. The model of the statue of the Queen as it rests in the artist's studio in the west-end of London overlooks a finished white marble statue of the late Professor Huxley, which is intended for the Natural History Museum at South Kensington, and near it lies a white marble bust of Sir William Agnew, executed for a private client.

New Patents.

These patents are open to opposition until March 17th.

1898.—Refuse Destroyers.—21,688. J. A. BAKER and W. R. BAKER; both of London, E.C. In this destructor the draught of foul gases is diverted first before it arrives at the end of its path and is led upwards through the incandescent layer on the last of a series of grates before being allowed to pass out of the destructor. This has a tendency to lift up the fuel and prevent clogging. Another feature of the invention is a mechanical elevator arranged in an inclined passage, up which the air draught flows to the furnace; this passage is heated.

1899.—Automatic Delivery and Discharge of Sewage.—941. E. BROWN, Burgess Hill, Sussex. This apparatus is an adaptation of the principle which obtains in the ordinary ball cock. For operating the valves for admitting the sewage and those for discharging it, floats are provided connected with a beam on a horizontal rocking shaft that is connected to the sewage inlet and discharge valves, so as to close the one set while opening the other. Devices are arranged to prevent the floats acting until the liquid has reached a predetermined level.

Waste Pipes.—3,342. J. SMITH, Addingham. To prevent it becoming damaged, and to prevent the entrance of wind and foul gases, there is fitted on the end of the pipe a cast-iron barrel, having its outer end inclined and covered by a pivoted flap, which remains normally closed.

Gas Burners for Heating Apparatus.—3,552. B. J. B. MILLS, London, W.C. (*La Société Anonyme des Fontaines à Gaz, Fontaines-sur-Saône.*) The supply of air is obtained by the combustion of the gas burning on the surface of one or several wire-gauze tubes, arranged horizontally or vertically, the supply being obtained partly through the gauze and partly through exterior openings arranged around the jets supplying gas to the burners. The gauze is held at one end by movable sleeves, which enable it to be renewed easily.

Brick Machines.—3,653. J. C. EDWARDS, Ruabon. This is an improved machine for

moulding and pressing bricks of the "double panel" type, and it consists essentially of a cam motion for operating the pressing mechanism and actuating the device for lifting the pressed brick out of the mould.

Cutters for Dressing Slates, Tiles, &c.—5,177. T. ADAMSON, Southport. This invention consists of a cutter bed having two parallel sides and channelled cross-pieces in combination with a lever carrying or forming a knife or guillotine. The cut is said to be clean and easy.

Adjusting Cutting Irons.—5,307. A. T. SOUTHERN and C. F. SPILSBURY; both of Birmingham. This device consists of a square screw pivoted to the body of the tool, over which fits a slide connected with the cutting iron. A nut engages with this slide, and so enables the "cut" to be adjusted as desired.

Windows.—23,616. A. MCKINNON, Hartwood, N.B. To do away with counter-balance weights, the sashes are connected with a cord at each end and so balance one another; but to prevent the one being raised whilst the other was lowered, the sash line is connected to a slide controlled by a knob on the window stile. Means are also provided for reversing the sashes.

The following specifications were published on Saturday last, and are open to opposition until March 24th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—1,374, SHORLAND, spindles for door handles and means for attaching them. 1,375, COOK, guards or shields for circular saws. 1,497, RODNEY and LLEWELLYN, locks and catches for doors. 1,565, HURRY and SEAMAN, rotary furnaces. 1,618, BUCHANAN and THOMPSON, inclined stepped elevator or moving stairway. 1,735, LINDLEY, cover for disinfecting and preventing smells from drains and sewers. 1,737, CADETT and LYON, ventilating buildings. 2,255, BUCHANAN, staircases and inclined ways. 2,803, BLACKHURST, screw connections for brass vases and knobs. 3,209, BARKER, screws and turn-screws. 3,916, CLARK, syphon flushing cisterns. 4,383, BAER, means for holding smoke pipes and chimney pots in chimney openings. 4,736, BADIN, bricks or tiles for floors. 4,813, WHITE, manufacture of Portland cement. 5,143, AYNLEY and FELL, portable spray-producing appliances for use in decorating ceramic ware. 5,764, NURSE, apparatus for consuming smoke. 6,293, DRUMMOND, automatic regulating apparatus for heating and ventilating buildings. 6,526, HORST, folding armchairs for theatres, &c. 7,000, WALKER, window sashes. 7,690, BIEKBECK (*Simmons*), hones or whetstones. 7,836, REID, flushing apparatus for water closets. 8,642, SKENE, pavement lights. 8,775, LACHMAN, electric incandescent lamp fittings. 8,861, FIRTH, backs of domestic stoves and kitchen ranges. 17,014, DISMUKES, means for coupling rails and posts. 17,608, manufacture of cement. 19,468, FRANK, casting process and apparatus. 20,759, BARNARD, treatment of sewage. 22,357, HANEMANN, pumps. 22,651, WILLMORE, staircases. 22,817, SCHROEDER, ovens or kilns for ceramic ware. 22,852, ALLDAY and EAGER, pulley blocks and hoists. 22,904, OLMESDAHL, machine for bending and cutting lock springs. 22,907, GIBBONS, door locks. 23,131, BAUM, pump for domestic use. 23,468, SUCHIER, self-regulating stove. 23,562, ORMEROD, smoke consumers for furnaces. 23,590, KELLY and KELLY, self-closing mechanism for doors. 23,914, HUME, soldering machine. 24,181 CROCKER, implements for scraping paint or varnish from railway cars and furniture. 24,875, SEMMER, glass grinding and polishing machine. 24,997, PAETOW, taps for water pipes.

The Great Paris Gateway.—The principal entrance to the Paris Exhibition will be a gigantic gateway at the beginning of the Champs Elysées crowned by a statue by M. Moreau-Vauthier. It represents the city of Paris and is a female figure attired in present-day costume. It is expected that its erection will be the signal for much criticism.

THE NEW TUGELA BRIDGES.

SOME particulars have already been given of the new Colenso bridge, but further details are now forthcoming (in "Feilden's Magazine") of the two bridges that have been so rapidly made by the Patent Shaft and Axletree Company, Ltd., of Wednesbury.

The Colenso bridge will consist of five spans, and the Frere bridge of two spans, each span being 105 ft. The width is 16 ft., a similar distance separating the foot of the girders and the top of the arch bracing. Each span consists of two large lattice girders braced together with cross girders, a system of overhead bracing being also adopted. Each span will weigh some 105 tons exclusive of rivets, and 69,000 rivet holes have to be drilled. Siemens-Martin steel, manufactured at the company's works, is used throughout, and the whole painted over with Docker's special "Hermator" oxide paint. Each bridge will accommodate a single line of railway of 3 ft. 6 in. gauge, and a further space at each side of 4 ft. 6 in. to serve for pedestrian or vehicular traffic.

In a single span there are 53 tons of plates, 13 tons of bars, 26 tons of angles, and 13 tons of tees. The weight of the two bridges is 735 tons, and, in addition to drilling and rivetting, about 52,500 ft. of rough edges of plates, &c., have to be planed. When fixed up, each span has to bear a test load of 264 tons, and, having satisfied that requirement, is regarded as being equal to the carriage of ordinary traffic up to 130 tons. The steel is also subjected to a tensile test, and has to endure a strain of 27 to 32 tons to the square inch. The Athara bridge, which was supplied in six weeks, weighed 400 tons, and the accomplishment of such a heavy piece of work in that time was regarded as phenomenal. In the present instance the first span was completed in about a fortnight, with nothing but ingots in stock when the order was received, and it is anticipated that the remaining spans will be sent out at the rate of one each week. The work should, therefore, be completed in about eight weeks, or two weeks longer than the American "record." These bridges, however, weigh about 335 tons more than the Athara bridge, the edges of the plates of which were not planed or finished.

The directors of the Company have taken a special interest in the construction of the bridge, and all employees, from the manager downwards, have worked and are working at an exceptional pressure, the template staff working voluntarily right through the Christmas holidays. A visit was paid to the works on Saturday last by the Birmingham and District Clerks of Works and Builders' Formen's Association, together with some of the Corporation officials.

A New Technical Institute at Tunbridge Wells is proposed to be erected and plans have been prepared by the architect, Mr. Hare, who reports that a satisfactory building can be erected for £11,000, with an additional £1,000 for equipment and furniture. The plans are to be submitted to the Kent County Council, and, if approved by that body and the Tunbridge Wells Council, an application will as soon as possible be made to the Local Government Board for sanction to borrow £12,000. If there is no opposition, it is hoped to have the proposed new institute ready by the end of next year.

The Greyfriars Church Question.—The question of the extension of Marischal College came before the Aberdeen Corporation on February 6th, in connection with the subject of the erection of a new church for Greyfriars' congregation. It was resolved, by a majority of twenty-one to ten, to approve of the scheme of extension recommended by the University Court, and to buy properties in Queen Street for a site for the church at a cost of £10,065, provided (among other conditions) that the University Court defray the cost of the erection of the church and tower, so far as such cost may exceed £10,000, and undertake, in carrying out the building scheme, to proceed first with the block extending from the new church along Broad Street.

Professional Practice.

Birmingham.—At the request of the Social Science Sub-Committee of the Royal Commission for the Paris Exhibition, the Improvement Department of the Corporation are preparing for exhibition a model of the workmen's dwellings which they are erecting in Milk Street. The model, which is about 16in. in height and 2ft. 8in. long, is an exact copy of the buildings. It is constructed of wood, and shows a section of a terrace comprising six houses, three on the ground floor and three above. Everything is carried out to scale, and each portion of the building is reproduced in the model. The latter, therefore, affords an admirable illustration of what is being attempted in the way of cheap housing. The verandah,

out under the direction of Mr J. Tart. The work of erecting the houses in Milk Street is progressing favourably, and they will be ready for occupation towards the end of March. The dwellings are built in terraces, one behind another, at a distance of 30ft. The total cost of the buildings, together with the cost of making the street and laying the sewers, will be about £10,100.

Blyth.—The new Theatre Royal built for the Blyth Theatre Company, at a cost of £13,000, was opened last week. The theatre has been designed by Mr. William Hope and Mr. J. C. Maxwell, of Newcastle-on-Tyne. The house consists of pit, stalls, circle, and gallery. The stage dimensions are 40ft. by 56ft., the height to grid being 50ft. There are spacious and convenient dressing rooms, with hot and cold

to the Grafton Street house, which they immediately adjoin behind, they will form a complete series of warerooms 350ft. long and five storeys high, or the entire length of Duke Street, with two frontages, one in Grafton Street and the other in Dawson Street. The building work is being carried out by Messrs. S. H. Bolton and Sons.

London.—The recent appeal case of *Chambers v. Goldthorpe* raised a question as to the position of an architect under a contract between a building owner and builder, where the architect had to certify before payment was made, and whether the architect could be sued for negligence, or was in the position of an independent arbitrator. The plaintiff, an architect, sued for his fees. Defendant counter-claimed for negligent measurement, by

ALLIANCE ASSURANCE COMPANY'S BUILDING, KING STREET AND CROSS STREET, MANCHESTER. CHARLES HEATHCOTE, ARCHITECT.

running along the first storey, gives a distinctive and somewhat superior character to the houses, and enables each occupant to have a separate entrance door. It is this privacy and completeness which distinguishes the buildings from flats, and they are generally known and more accurately described as dual houses. Each house is self-contained and comprises a front room, a bedroom, a scullery, a small coal-house, and a water-closet; while each alternate dwelling has an additional bedroom, the occupant of the larger dwelling having to pay 4s. 6d. rent as compared with 3s. for the smaller house. An admirable feature in the construction of the dwellings is their arrangement, by which the whole place is under cover, and the buildings have been designed with a view to compactness, comfort, and convenience. The construction of the model has been a laborious task, and the work has been carried

water, and there is a large property room and scene dock. A lift is provided to convey artists' luggage to each floor. The builders were Messrs. J. and W. Simpson, of Blyth. The decorations have been carried out by Messrs. Dean and Co. The theatre is estimated to seat 2,000.

Dublin.—Under the direction of Sir Thomas Deane and Sons, architects, No. 56, Dawson Street is at present being rebuilt for Messrs. Millar and Beatty, Limited. The entire block of buildings has been removed, and after excavating, so as to give a basement storey, it will be all rebuilt on modern lines as a fully-equipped furniture warehouse. The new premises will have a frontage and a depth of 170ft., varying in width, when joined to the rear portion of No. 55, from 25ft. to 60ft. When the new premises in Dawson Street are added

reason of which he was obliged to pay more than he rightly should have paid, the damages, if recoverable, being assessed at £15. It was contended that while in some sense the architect might be a quasi-arbitrator, yet the building owner might bring an action against him for negligence, though the builder could not. Mr. Scott Fox (for the plaintiff) said it was against public policy that a person who was in the position of a quasi-arbitrator should have to perform his duties under fear of an action. If the defendant were dissatisfied with the plaintiff's measurements his proper course was to call in another architect. Mr. Justice Channell, in giving judgment, said that where a person was in the position of a quasi-arbitrator an action could not be brought against him for negligence in the exercise of his duties, and, wherever that doctrine applied, it was not ousted by the fact that the

arbitrator was under a contractual relationship with one of the parties, by whom his fees were paid. Therefore, the appeal must be allowed. Mr. Justice Bucknill concurred, and the appeal was allowed with costs.

Manchester.—The Alliance Assurance Company's new building in Manchester is built externally of stone, and the offices are entered from King Street. The entrance in the Cross Street front gives access to the upper floors only. The staircase is well lighted and has the walls lined throughout with faience. In the centre of the staircase well is a passenger lift. The architect was Mr. Charles Heathcote, of Manchester, and the builders were Messrs. Neill and Sons.

Norwich.—The total estimated cost of restoring and refitting Worstead Church is about £5,500, and the work is being done as funds permit, it having been wisely resolved that nothing shall be begun till the money is in hand to pay for it. The church belongs to the transitional period between Decorated and Perpendicular, and comprises nave, with aisles and clerestory, chancel, and south porch. Its fine embattled tower, containing six bells and a clock, rises 109ft. and is surmounted by four lofty pinnacles, which were erected in 1861 to replace four others put up in 1844. The outside stonework is chiefly of flint. The entrance porch under the door and the great west window above it are richly ornamented with mouldings and tracery. The chancel is separated from the nave by a beautiful rood screen, erected in 1512, the lower panels of which are adorned with paintings of apostles and saints. Mr. T. Leonard Jenkins (the present vicar) found that there were many things to be done if the structure was to be saved from certain ruin. A report of the late Sir Arthur Blomfield was obtained, according to which the first duty was the restoration of the nave roof, the remaining work being successively the repair of the tower, which is really unsafe and a portion of which has fallen, the repair of the north aisle roof and the porch, the heating and re-seating of the church, and the re-hanging of the bells. According to Sir Arthur Blomfield's designs, which cover the whole of the work in contemplation, the east end has been beautifully decorated, the funds being provided by the early communicants. Now the nave roof has been restored at a cost of £1,070, some £600 of it being subscribed by people living in the parish.

Preston.—The new Sessions House now being erected is in Harris Street, with a frontage to Lancaster Road. In the locality near the site great changes have recently been made. The Old Shambles, where the first post office the town ever boasted was conducted, has been replaced by a handsome arcade, and the Harris Free Library and Museum. That change brought about the abolition of over a dozen old-fashioned licensed houses. There is now a square, which has upon the north side the Town Hall, on the east side the Library and Museum, and on the west commercial houses, whilst the north is to be occupied by a new post office, the plans for which have recently been passed. The Sessions House is in the angle between the post office and the Museum. The design has been prepared by Mr. H. Littler, the county architect. The main entrance will be from Harris Street, and over the porch a tower will rise to a height of 165ft. The frontage of the block will be 180ft, whilst from front to back the distance will be 100ft. The exterior masonry will be of Longridge stone throughout, and the building is in the English Renaissance style, well relieved with columns and carving. It will be erected over a granite base, and will be three storeys high. Through the entrance porch vestibule is the assembly hall, which is to be lighted by means of a circular-headed window. From here the main staircase ascends to the courts. This staircase will be one of the chief features of the interior. It is to be of Hopton Wood stone to match the facings of the hall, and the steps will be of granite. The ceiling, which

is to be decorated, will be constructed of fibrous plaster. There are to be two sessions courts, the public entrance to which will be from Lancaster Road, and they are to be on the second level. The assembly hall, to which the main staircase leads, will be of stone from the Stancliffe quarries. Its size will be considerable, and it will be domed. The height from the floor to the top of the structure will be 38ft., and at the far end of the hall will be two large stone columns, to assist in supporting the weight of the upper floor. The hall is to be tiled, and the corridors will be floored in the same way. From this hall a corridor will run round the entire building. The courts are to be on each side of the hall, with entrances from the corridors. The dimensions of each will be 49ft. long, 39ft. broad, 32ft. high. The decoration will be carried out in a manner promoting easy ventilation. From the floor to a height of 8ft. the walls will be tiled. Over this is to be a dado of oak panelling to the height of 25ft. The ceiling will be studded with ceiling lights, and a glass roof will be placed on the exterior. Added to this will be the light derived from windows on the north side. The floor will be parquet. Each court will be exactly similar, and immediately in the rear will be the chairman's rooms and the private rooms of the clerk of the peace. On the side corridor is to be the magistrates' room, the grand jury room and ante-room, and on the right hand side of the assembly hall will be the barristers' library, robing room, consulting room, and other rooms. On the third floor are the living rooms, including a dining room 55ft. by 25ft., very lofty and well lighted. At the front of the building on the ground floor will be the record rooms and other offices, and in close proximity are quarters for the prison warders. The cells will be on the basement floor, with other prison accommodation. A special entrance at the rear is provided for the prison van. The building will be lighted throughout with electricity and heated by hot water at low pressure. The provision for the electric light plant and the heating apparatus is to be the only accommodation below the level of the street. The cost of the building will probably be about £75,000, and it is hoped that the edifice may be completed by 1902.

York.—A new wing is being erected at the Friends' Boys' School at Bootham, York, from designs by Mr. William H. Thorp, architect, of 61, Albion Street, Leeds. A new science block is being built at the south-east corner of the cricket field, comprising a laboratory, lecture room, science master's preparation room, &c. Two five-courts, one open and one closed, are to be formed in connection with this block. On the site of the buildings which were destroyed by fire last May a block is now being erected which will contain a larger gymnasium, two workshops, two natural history rooms, &c. It is understood that when these two blocks have been completed, and, in case sufficient funds are forthcoming, the committee propose to effect improvements in the existing school-room block to include a suite of good classrooms, a large assembly hall, to be called the John Bright Hall in memory of the great statesman who was formerly a scholar at the institution, and a library. A further scheme is suggested by which considerable improvements would be effected in the premises on their city side. The cost of these works is estimated at about £14,000.

Dewsbury Infectious Hospital.—From what transpired at a meeting last week of the Dewsbury Joint Hospital Board, it appears that the infectious hospital to be erected very shortly near Earlsheaton will cost £23,000.

More Fire Tests.—At the British Fire Prevention Committee's testing station on Wednesday last tests were made with two solid (three thicknesses) wood doors and a floor of fir joists with 5in. concrete filling. Details will be given when the official report is published. Unfortunately, during the floor test, Mr. E. R. Farrow was somewhat seriously burnt in the right eye.

New Companies.

British and North American Timber Co., Limited.

This company was registered on January 24th by Edmunds and Rutherford, 19, Great Winchester Street, E.C., with a capital of £20,000 in £1 shares, to carry on business as timber shippers, brokers, and importers, agents for the sale of or dealing with timber or wood goods. The directors are Hon. W. C. Pepys, H. W. Holland, W. P. Thompson, and S. de C. Thompson. Qualification, £200. Remuneration, £52 10s. each, to be increased according to profits.

Smith Brothers (Burnley), Limited.

This company was registered on January 25th by Proctor and Co., 3, Gresham Street, E.C., with a capital of £10,000 in £10 shares, to acquire as a going concern the business of builders and contractors as now carried on by Smith Brothers at East Rain Place, Burnley, Lancashire. The directors are E. S. and G. Smith. Qualification, 50 shares. Remuneration to be fixed by the company.

Thomas Wragg and Sons, Limited.

This company was registered on January 29th by Andrew Wood and Co., 8 and 9, Great James Street, Bedford Row, W.C., with a capital of £150,000 in £5 shares, to acquire the business carried on at Swadlincote, Derbyshire, under the style or firm of Thomas Wragg and Sons, and, generally, to carry on in all or any of their respective branches the businesses of manufacturers of and dealers in firebricks, fireclay, glazed bricks, blue bricks, building bricks, floor and roofing tiles, glazed stoneware and earthenware sanitary pipes and fittings, baths, sinks, lavatories, closets, porcelain, earthenware, and all other kinds of bricks, tiles, clay, and goods and appliances for plumbers, sanitary engineers, builders, contractors, and others; as quarry owners, sanitary engineers, sanitary sewage works, waterworks, road making, and general contractors; dealers in sand, lime, and cement; as cabinet-makers, carpenters, builders, timber merchants, engineers, and workers in any kind of wood and metal; &c. The first directors (of whom there shall be not less than three) are J. D. Wragg, E. B. Wragg and H. Wragg. Qualification, £1,000. Remuneration, £50 per annum each.

Eglinton Limestone Company, Limited.

This company has been registered in Scotland, with a capital of £12,000 in £1 shares, to carry on the business of miners, quarrymasters, lime burners, brick manufacturers, &c., at Glenarm, county Antrim, Ireland. Registered office: 212, West George Street, Glasgow.

C. Evans and Company, Limited.

This company was registered on January 30th by Gadsden and Co., 28, Bedford Row, W.C., with a capital of £10,000 in £1 shares, to adopt a certain agreement for the acquisition of the business of Charles Evans, and to carry on business of mechanical, electrical, and general engineers; brass and iron foundries, builders' merchants, and ironmongers, &c.

Newport Enamelled Slate Co., Limited.

This company was registered on February 5th by Warriner and Co., 188, Fleet Street, E.C., with 20 members, each liable for £1, to carry on the business of manufacturers of and dealers in enamelled and plain slate, granite, stone, marble and hardware goods; as ironmongers, metallurgists, engineers, &c. Registered office: Chepstow Road, Newport, Monmouth.

South Wales Sanitary Inspectors.—The annual meeting of the South Wales and Monmouthshire Sanitary Inspectors Association was held at Neath on Saturday. Dr. Williams, Cardiff, was re-elected president, and Dr. Walford and Dr. Herbert Jones vice-presidents.

THE GLASGOW EXHIBITION.

THE Glasgow International Exhibition of 1901 (it will be opened in May) promises to be a great success. The total area occupied by buildings, temporary and permanent, will be 13½ acres, of which the Industrial Hall and Grand Avenue will occupy 28,842 sq. yds.; the Machinery Hall, 19,277 sq. yds.; the Art Galleries, 8,667 sq. yds.; the Refreshment Department, 5,556 sq. yds.; and the Grand Hall, 2,178 sq. yds. To show the international character of the exhibition, it may be mentioned that France has taken up about 10,000 sq. ft., Canada and Queensland half as much, India rather less than Canada, and Japan 2,000 sq. ft. The Governments of the United States, Russia, Persia, and Morocco have intimated their intention of exhibiting.

From an artistic and decorative point of view one could not select a more promising group than India, Russia, Japan, Persia, and Morocco. Of the free space in the Industrial Hall and Grand Avenue, amounting in all to about 114,000 sq. ft., British exhibits will absorb 60,000 sq. ft., those of British possessions 9,500 sq. ft., while foreign exhibits will take up the balance of 44,500 sq. ft., or rather more than a third of the entire space. The provisional allocation of the machinery space is almost exactly in the proportion of 3ft. for British exhibits to every foot allotted abroad. Taking these two departments together, the estimated rental at 8s. per square foot is £29,000.

The Kelvingrove Art Gallery and Museum will occupy a central position. In style the building is Jacobean, freely treated, and the entire block measures 800ft. by 200ft. Two well-proportioned towers, rising to a height of 150ft., flank the top of the central hall, and combine with cupolas at the four corners of the building to form an effective sky-line. Here will be housed Glasgow's own art treasures, and an international loan exhibit illustrating the art of the nineteenth century. A large amount of space will also be given here to archaeology and Scottish history, and the Art Galleries will include an Educational Section. With regard to amusements, one of the projects under consideration is the erection of a revolving tower, 150ft. high, on the slopes of Gilmore Hill, which will afford a magnificent panoramic view by day and light the grounds by night.

The best of the fourteen competitive designs for the exhibition building was sent in by Mr. James Miller, I.A., Glasgow, and the first sod was cut on April 22nd, 1899. Looking at the exhibition from the slopes of Gilmore Hill, in the foreground there will be pavilions, kiosks, bandstands, fountains, and many restaurants, no refreshment rooms being contained in the main buildings, which are of light design. The Kelvin, spanned by two bridges, divides the picture. To the right a broad overhead bridge, crossing Dumbarton Road, connects Kelvingrove Park with Bunhouse grounds, where a lofty building is set apart for the machinery section.

The Nottingham Master Builders' Association held its annual dinner on Friday last, when the vice-president, Mr. H. Vickers, took the chair.

New Buildings in Nottingham.—The Nottinghamshire Miners' Association are about to build three houses, a suite of offices, and a miners' hall at New Basford, Nottingham. The architect is Mr. Henry Harper, of Regent Chambers, Market Place, Nottingham.

The Birmingham Municipal School of Art has opened at the rooms of the Birmingham Royal Society of Artists an exhibition of students' work, which will remain open till Saturday next. The exhibits of the department devoted to architecture and building construction show that this section is a strong one. There are now at the Central School about two hundred students engaged in architects' and builders' offices, who, under Mr. W. H. Bidlake, assisted by Mr. H. T. Buckland, are turning out work of a very superior character.

Keystones.

Aberdeen Art Gallery is to be transferred to the Corporation.

A New Board School at Machynlleth is to be built at a cost of about £3,500.

Chichester Cathedral.—Contributions are now being sought towards the cost of completing the north-west tower.

The new Church at Shaldon is to be completed forthwith at a cost of about £6,000. Mr. Edmund Sedding is the architect.

An Exhibition of Artistic Steel and Iron Work has been opened at the Burlington Fine Arts Club, 17, Savile Row, W.

A Winter Garden Scheme for Dundee, similar to that at Glasgow Green, is being considered. It is estimated to cost £5,000.

At St. Werburgh's Church, Derby, a new reredos has been erected at a cost of about £1,000. It was given by Mr. H. T. Alton, of Abbott's Hill, Derby.

New Schools at Manor Park, E.C., are about to be erected by the Little Ilford School Board at a cost of over £20,000. The architect is Mr. S. Jackson, of 65, Fenchurch Street, E.C.

A Pocket Directory of Edinburgh and Leith, including a time table and a map, has been sent us by Mr. W. Sinclair, of 12, Shandwick Place, Edinburgh. It only costs a penny, and is very handy.

Reparation or Vandalism?—The statues that decorate the west front of the Cathedral of Notre Dame in Paris have recently undergone restoration, and the sculptors employed in the work have just completed their task.

Italian Tribute to Ruskin.—The Venice Municipal Council has conveyed an expression of its condolence to the family of the late Mr. John Ruskin, and will affix a memorial tablet to the house in Venice in which the celebrated writer lived while in that city.

Matriculation Directory.—We have received a copy of this useful publication, containing articles on the special subjects for June, 1900, and January and June, 1901. It also comprises solutions to the examinations held last month, and the University Correspondence College Calendar.

Hull Central Square Scheme.—Notices to quit are to be given to the tenants occupying the blocks of buildings bounded by Carr Lane, Waterworks Street, Junction Street, and Little Chariot Street, Hull. These blocks the Corporation contemplate pulling down for the making of a great central square and other improvements.

The Thornton-Pickard Manufacturing Co., Ltd., of Altrincham, whose photographic shutter is so well-known, send us a copy of their 1900 catalogue. We notice particulars of a new competition (closing October 1st next) in which £105 are offered in prizes. A copy of the catalogue will be sent post-free on application.

Proposed Police Convalescent Home, Harrogate: Result of Competition.—The result of this competition has been as follows: First, Mr. H. S. Chorley (Messrs. Chorley, Conin and Co., 15, Park Row, Leeds); second, Mr. Edward C. Maidman, 13, South Charlotte Street, Edinburgh; and third, Messrs. Chorley, Conin and Co., 15, Park Road, Leeds. Mr. H. S. Chorley was appointed architect.

Enlargement of Wakefield Cathedral.—At a meeting of the Wakefield Cathedral Extension Committee tenders were considered for the works required in connection with the enlargement of the cathedral as a memorial to the late Rev. Dr. Walsham How, the first bishop of the diocese. Eleven tenders had been received, and ultimately it was resolved—"That the honorary secretaries be empowered to enter into a contract with Messrs. Armitage and Hodgson, of Leeds, to build the Cathedral extension, at a cost of £24,373, but that the contract be divided into two, so that the first portion of the work, including chapter house and two vestries, be entirely completed before the second portion of the work is proceeded with."

Enfield Isolation Hospital, which has been erected at Winchmore Hill, at a cost of £25,000, was opened on Saturday.

A new Nurses' Home at Gateshead has been built in Coatsworth Road from designs by Messrs. L. H. and A. L. Armour, of Gateshead.

New Church for Edzell, Brechin.—A new Free church is proposed to be built at Edzell from designs, selected in competition, by Mr. P. H. Thomas, of Dundee.

Widening Temple Row, Birmingham.—A long discussion took place at last week's meeting of the Birmingham City Council on the recommendation of the Public Works Committee to purchase a strip of land around St. Phillip's churchyard, containing 1,116 sq. yds., for £5,580, for the widening of Temple Row, Temple Row West, and Colmore Row. The total cost of carrying out the improvement is estimated at £9,250, and the Finance Committee were eventually authorised to borrow that sum. The proposed alteration will secure a uniform width to the thoroughfare of 50ft., throwing in an average of 10ft.; when the new scheme for tramways is considered, a wide through street like this in the centre of the city will be of the very greatest advantage.

CONTRACTS OPEN.

METROPOLITAN ASYLUMS BOARD. TO BUILDERS.

The Metropolitan Asylums Board invite TENDERS for the ERECTION of a HOSPITAL at Joyce Green, near Dartford, Kent, according to drawings, specification, articles of agreement, and schedule of conditions, which may be seen at the Offices of the Architects, Messrs. A. and C. HARSTON, 15, Leadenhall-street, E.C.3., between the hours of TEN and FIVE.

Bills of quantities, prepared by Mr. W. T. Farthing, may be obtained at the offices of the Architects, as above, upon payment of a deposit of £10 in gold or Bank of England notes, which will be returned to persons sending in a bona-fide Tender with the priced bills of quantities.

Tenders, sealed and endorsed "Tender for Joyce Green Hospital," must be delivered at the Office of the

Board, Norfolk House, Norfolk-street, Strand, W.C., not later than TEN a.m. on WEDNESDAY, MARCH 14th, 1900.

The Board do not bind themselves to accept the lowest or any Tender.

By order,
 T. DUNCOMBE MANN,
 Clerk to the Board.

January, 1900.

EGHAM SCHOOL BOARD. TO BUILDERS.

The Egham School Board invite TENDERS for the CARRYING-OUT of certain ALTERATIONS and ADDITIONS, &c., to the Egham Hythe Schools, Thorpe-road, Staines.

The drawings, specification, and quantities of contract can be seen at the offices of the Clerk to the School Board between TEN and FIVE p.m., where forms of Tender can be obtained.

Tenders sealed and endorsed "Alterations and Additions Egham Hythe Schools, Thorpe-road, Staines," to be delivered at the Offices of the Clerk to the School Board not later than FOUR p.m. on FEBRUARY 19th, 1900.

The Board do not bind themselves to accept the lowest or any Tender.

Sureties will be required for the due performance of the contract, and in the case of all persons Tendering their names to be submitted with the Tender.

By order,
 JOHN ANTHONY ENGALL,
 Clerk to the Board.

Clarence-street, Staines.
 January, 1900.

COMPETITIONS.

BOROUGH of WEST HARTLEPOOL. TO ARCHITECTS.

THE CAMERON MEMORIAL ACCIDENT AND GENERAL HOSPITAL COMPETITION.

The Committee of the above Hospital invite COMPETITIVE PLANS for the erection of an ACCIDENT and GENERAL HOSPITAL at a cost not exceeding £12,000.

Premiums of One Hundred Pounds and Fifty Pounds will be awarded to the authors of the design being placed first and second respectively, and in the event of the selected design being carried out the premium will merge into the commission.

The President of the Royal Institute of British Architects will be asked to appoint an assessor to advise upon the designs.

Copy of conditions and instructions, together with site plan, may be obtained upon application to the undersigned.

The drawing must be delivered under cover, addressed to the Chairman of the Cameron Hospital Committee, Municipal Buildings, West Hartlepool, not later than WEDNESDAY, APRIL 11th, 1900.

By order,
 J. W. BROWN,
 Borough Engineer.

Borough Engineer's Office,
 February, 1900.

BOROUGH of RAWTENSTALL. OPEN COMPETITION FOR LAYING OUT PARK AND PLAYGROUND. TO ARCHITECTS, LANDSCAPE GARDENERS, AND OTHERS.

The Committee appointed for the purpose of LAYING OUT and EQUIPPING the proposed Park and Playground at Oak Hill, Rawtenstall, invite Architects Landscape Gardeners, and others to send in COMPETITIVE PLANS, &c., for Laying Out and Equipping the same, and offer the following Premiums for Plans adjudged of sufficient merit and passed First, Second, and Third in order respectively, namely: First Premium, £50; Second Premium, £30; Third Premium, £20.

The premiated drawings will become the absolute property of the Committee, and the successful com-

petitor may be selected to carry out the work, in which case the premium will merge in the commission.

The Committee will be assisted with professional advice when adjudicating on the plans.

Copy of conditions and Plan of site may be obtained on application to Mr. A. W. LAWSON, A.M.Inst.C.E., Borough Surveyor, Municipal Offices, Rawtenstall, on payment of £2, which will be returned on receipt of Competitive Plans, &c.

Plans, &c., must be delivered as directed in the conditions at the Municipal Offices, Rawtenstall, on or before FRIDAY, MARCH 30th, 1900.

By order,

JAMES WHALLEY,
Town Clerk.

Municipal Offices, Rawtenstall.
January, 1900.

NON-FLAMMABLE WOOD

Or Wood that has been chemically treated so that it Won't
Catch Fire and Won't Spread Flames.

The London Non-Flammable Wood Co. Ltd.

beg to announce that their works in London, the first erected in Europe, are now complete, and they are prepared to supply Non-Flammable Wood in any quantity.

NON-FLAMMABLE WOOD.

BOARDS HAVE BEEN OFFICIALLY TESTED BY THE BRITISH FIRE PREVENTION COMMITTEE.

The Committee's Report says:—

"No incandescence or spread of flame was observed, nor did the material, as far as could be seen, contribute in any way to the spread of flame. The surface of the boards was charred."

NON-FLAMMABLE WOOD JOINERY and CABINET WORK has been specified by leading Architects, and the Company has fulfilled orders for the Royal Yacht, the Admiralty, the Crystal Palace, Mr. Wyndham's Theatre, etc., etc.

LIFT-SHAFT LININGS FOR FLATS AND HOTELS.

Use Non-Flammable Wood Matchboarding.

NO FIRE RISKS. NO PLASTERING. NO WASTE OF TIME.

Quotations will be furnished on receipt of Specifications.

THE LONDON NON-FLAMMABLE WOOD COMPANY Limited,

Regent House, Regent Street, London, W.

BUILDERS' LIFTING APPLIANCES.*

By DAVID SKINNER.

AT the outset it may be stated that in this case the word "builder" means any tradesman in a building where lifting appliances are required; and this may apply to new buildings or to old buildings undergoing repairs, alterations, such as slapping, shoring, and underpinning for shop fronts, &c.

This paper is written mainly to consider the mechanical advantages that may be gained by the use of levers, crabs, cranes, lifting jacks, pulley blocks and other contrivances.

A knowledge of the mechanism of these appliances is of equal importance to the craftsman as that of his ordinary tools. Too much is taken for granted in what is known of these machines. A plate is fixed on the body of a crane, indicating the safe load that may be lifted by the crane, but we do not know under what conditions the result was ascertained. A crane with the jib inclined at, say, 60deg. to the ground will

$P \times AF = W \times BF$, or $P : W :: BF : AF$, also $\frac{P}{W} = \frac{BF}{AF}$. In other words, if AF is twice BF , then to have equilibrium the power will be half the weight. Fig. 2 represents a lever of the second order, where W is between P and F . The moments of P and W must be equal in order that the lever may be in equilibrium.

This statement will be more easily understood if we consider this lever as a beam resting on both ends A and F , when it will be clear that both reactions are acting upwards and the amount of each is:—at A , $\frac{BF}{AF}$ and

at F , $\frac{AB}{AF}$ or $P = \frac{BF}{AF} W$. Fig. 3 represents a lever of the third order, P being between W and F ; therefore the power necessary to balance the weight will be greater than the weight, and is found by taking the length of the arm of P and multiplying by its distance from F , and the arm of W by its distance from F and by the amount of W ; these two should be equal; $\therefore P \times AF = W \times BF$.

The following is another way of considering the equilibrium of a lever:—Suppose AB (Fig. 4) to be a lever without weight acted upon by weights P and W . If the lever be moved through a small space so as to be in the position shown by the dotted lines, then P will have moved through the space CD , and W through the space EG ; therefore the work of P will be $P \times CD$, and that of W will be $W \times EG$; but these will be equal, as shown thus:— $P \times AF = W \times BF \therefore \frac{P}{W} = \frac{BF}{AF} = \frac{EG}{CD}$. $\therefore P \times CD = W \times EG$. The principle of the equality of work at the points of application of P and W is of the greatest use in the solving of mechanical problems and applies in all cases.

The Wheel and Axle.

There is an objection to the use of arrangements of ordinary levers in cases where the weight has to be raised through a considerable distance. To overcome this the wheel and axle may be used; it is really a form of lever by which W may be raised through any desired space. Fig. 5, shows a front and side elevation of a wheel (C) and axle (D). The principle is precisely the same if the wheel is replaced by a handle secured to the shaft, as in an ordinary crane; in this case the machine is called a windlass. The weight W hangs by a cord or chain which is secured to and wound round the axle. The wheel and axle revolve upon a shaft (of which F is the centre), supported by suitable bearings, as shown. On reference to the side elevation it will be seen that the arrangement is equivalent to a lever AFB of which the fulcrum is at F , the power being applied at A and the weight at B ; the condition of equilibrium is therefore the same as that of a simple lever, namely,

$$P \times AF = W \times BF \therefore \frac{P}{W} = \frac{BF}{AF} = \text{radius of axle}$$

radius of wheel; but as the circumferences of circles are in the proportion of their radii, $\frac{P}{W} = \frac{\text{circumference of axle}}{\text{circumference of wheel}}$. Example: Radius of wheel, 16in.; diameter of axle, 6in.; W , 2cwts. Find W . $P \times 16 = \frac{1}{2}$ of 6in. $\times W$ or 2cwts. = 16 $P = 3 \times 2$ cwts. $\therefore 3 \times 2 \times 7 = P$, or 42lbs. In the case of an ordinary lever where the arms are

given we have simply to deal with them, but in wheel and axle problems, and, it may be stated here, in all problems where a rope or chain is wound round a barrel or drum, the diameter or thickness of the rope or chain should be taken into account. We must also take the diameters of each part of the machine, or the radii or the circumferences; we cannot take the diameter of one part and the radius of another, and so on.

It is evident that a practical limit of size for wheel and axle machines would soon be reached, by which the limit to the gain in power which can be obtained is reached also. This difficulty can be overcome by introducing one or more pairs of wheels. Such an arrangement is called a crab; if there is one pair of wheels it is called a single-purchase crab, if two pairs a double-purchase crab, if three pairs a treble-purchase crab, and so on. Before we consider any of these purchase crabs, it will be necessary, in a general way, to take up wheel work in gear.

In calculating the diameters of toothed wheels in gear with one another, we measure the diameter of the pitch circle. The pitch circle of a wheel is the circle in which represents the motion of the wheel when in gear with other wheels, in which case the pitch circles would be continually in contact with each other during their rotation; and the point of contact of two wheels is called the pitch point. The pitch of the teeth in wheels is

the distance, measured on the pitch line, occupied by a tooth and a space together. Fig. 6 shows a wheel and pinion in gear, with their pitch circles shown dotted. These teeth should be uniform, for, if not fitting properly, the driving may be obtained by a series of blows on the teeth, instead of a continuous uniform pressure, the result being a loud noise and an irregular and injurious wearing on the teeth.

Figs. 7 and 8 illustrate a single-purchase crab. There are two cast-iron standards St , with suitable bearings for shafts, secured together by three stays S . The upper shaft C has square ends on which the handle H (to which the power is applied) is placed, and on this shaft there is also a pinion A gearing with a wheel B , which is keyed to the second shaft along with the barrel F . A ratchet wheel and detent are shown at D , their function being to prevent the weight running down on the removal of the power.

Determination of the proportion between P and W : (1) By principle of work; (2) by the lever principle. First, Fig. 9. Let the length of the handle be denoted by l , the diameter or number of teeth in pinion by A , the diameter or number of teeth in wheel by B , radius of barrel, drum or axle by r , and Π circumference in terms of diameter (Π in all cases in this paper is taken as 3.1416). Then the motion of W for one revolution of the barrel $2\Pi r$ and the work of W in the same time = $W \times 2\Pi r$; motion of P in the same time will be $2\Pi \times \frac{B}{A} \times \frac{r}{A}$ (being the number of revolutions that A makes for one of B , and,

have a different stress to resist when the jib is inclined at 45deg. Again, one man may or may not be able to lift a certain load according to the means he employs. The question of the materials composing these machines, their strength and suitability, will not be considered, as it would take up too much time and is rather outside the scope of this paper. Friction also will not be considered, as the amount of such friction, or, to use a technical term, the efficiency of a machine, can only be determined by experiment; and if an experiment were tried on two machines of the same mechanism the result would possibly show a difference, as much depends on the good condition in which these appliances are kept. An example will be given with each case considered, and a simple formula stated to calculate the mechanical advantage.

In considering levers, we find there are three kinds. Fig. 1 represents a lever of the first order, where P is a force acting downwards at A , keeping the lever in equilibrium under the action of the weight at B . The power is to the weight in the inverse proportion of their respective arms; thus

* A paper read before the Glasgow and West of Scotland Technical College Architectural Craftsmen's Society on January 26th, 1900.

therefore, for one of the barrel); and the work of P will be $P \times 2\pi \times \frac{B}{A}$; but these are equal, the arrangement being in equilibrium, $\therefore P \times 2\pi \times \frac{B}{A} = W \times 2\pi r$; dividing both sides of the equation by 2π we have $\frac{Pl \times B}{A} =$
 $Wr \therefore \frac{P}{W} = \frac{rA}{lB}$ or $P = \frac{WrA}{lB}$ and $W = \frac{PlB}{rA}$.
Or P is to W as radius of axle multiplied by the diameter or number of teeth in pinion is to the length of handle multiplied by the diameter or number of teeth in the wheel.
Second. On referring to Fig. 9 it will be seen that P acts in the circle in which the handle moves. If we denote the length of the handle by l , radius of pitch circle of pinion by A, radius of pitch circle of wheel by B, and radius of barrel by r , then the pressure P will produce a pressure Q from pinion A to wheel B, the handle and the radius of the pinion to point C acting as a bent lever. There will also be the reaction of wheel B upon pinion A acting along CQ; further, the moment of Q about the centre of wheel B must be the same as that of W about the same point, Q and W being forces acting on the arms of a second bent lever. We have, therefore, $Pl = QA$, and $QB = Wr$. But $Q = \frac{Pl}{A} \therefore QB = \frac{PlB}{A} \therefore \frac{PlB}{A} = Wr \therefore \frac{P}{W} = \frac{rA}{lB}$, as previously obtained. It is desirable to notice that the equation for W is $P \times \frac{l}{A} \times \frac{B}{r} = W$. A consideration of this will enable us to adopt a simple method of solving crab problems. It

double-purchase crab are here considered separate for the sake of clearness. The proportion between P and W is obtained in the same way as in the single-purchase crab, and we need hardly go over the statements again, but merely add the two extra pairs of wheels represented by C and D.
 $\therefore P \times \frac{l}{A} \times \frac{B}{C} \times \frac{D}{r} = W$, or $P : W :: r \times A \times C : l \times B \times D$.
Next we come to the determining of the proportion between P and W by principle of lever. Let length of handle be denoted by l , radius of pitch circles of pinions A and C by A and C, radius of pitch circles of wheels B and D by B and D, and radius of barrel by r . Q and R represent the forces acting between A and B and C and D respectively; then in first lever, $P \times l = A \times Q$, $\therefore Q = \frac{P \times l}{A}$; in the second lever, $Q \times B = R \times C \therefore \frac{P \times l}{A} \times B = R \times C \therefore R = \frac{P \times l \times B}{A \times C}$; in the third lever, $R \times D = W \times r \therefore \frac{P \times l \times B}{A \times C} \times D = W \times r \therefore P : W :: r \times A \times C : l \times B \times D$, the same as before. By using this last method we can determine the pressures on the wheel teeth. It will be observed that the pressures on the wheels increase as we approach W. It is for this reason that in a double-purchase crab the teeth of the barrel wheel and its pinion are made of a stronger pitch than the handle shaft pinion and wheel gearing with it. Example: A double - purchase

will be seen that the first factor is P, the second is $\frac{l}{A}$, and the third is $\frac{B}{r}$, these being the terms in the precise order that they are in the crab. Example: Single-purchase crab, handle, 16in. long; barrel, 8in. in diameter; pinion and wheel, 12 and 80 teeth respectively; weight, one ton; find power required. $P \times \frac{16}{12} \times \frac{80}{4} = 2,240\text{lbs.} \therefore 80P = 3 \times 2,240 = 6,720\text{lbs.} \therefore P = \frac{6,720}{80} = 84\text{lbs.}$
In a double-purchase crab, shown diagrammatically at Fig. 10 and in elevation at Fig. 11, we have an additional pair of wheels. The double-purchase crab may be used single purchase by putting it out of gear of the second pair of wheels. This is done by sliding the right-hand shaft endwise and putting the handle on the left-hand shaft. In crane work this arrangement is different, though the result is the same. The single- and

crab has wheels with 72 and 64 teeth, and pinions with 12 and 16 teeth respectively. The handle is 16in. long, and the barrel is of 6in. diameter. W is three tons. Find P. $\frac{P}{1} \times \frac{16}{12} \times \frac{72}{16} \times \frac{64}{3} = 3 \times 2,240\text{lbs.} = 52\frac{1}{2}\text{lbs.}$ Although not stated so, it will be understood that the pinions are the drivers and the wheels the followers. If the reverse were the case, then power would be lost instead of being gained, which is contrary to usual practice in the use of cranes, P generally being limited. Also, if the diameter of the rope is given, then half of its diameter must be added to the radius of the barrel.
Rope and Pulley Block Tackle.
It has already been shown that the principle of the wheel and axle is the same as that of a simple lever. If the wheel and axle are made of the same diameter, then the arms of P and W would be the same, and whatever was the motion of P, that of W would be similar. If

P and W are arranged to act in the same plane, then P may be applied to a rope or chain passing round a pulley, and W will be secured to the rope at a point on the opposite side of the pulley. The leverage of each will be the same, and P and W will be equal; therefore there is no gain in power. To go further, and add another pulley hung by a cord fixed to the under side of the first pulley; we then have two ropes supporting the weight and the pull or tension on the rope is equal throughout. Thus the tension on the two ropes supporting W (Fig. 12) is each equal to P, and the motion of P equals half the motion of W; therefore $W = 2P$, and $P = \frac{W}{2}$, or the mechanical advantage is 2, and the pull on the beam is $P + W$, or 3 P. Such an arrangement is called a pulley block, which may have two or three sheaves side by side, separated from each other by thin metal plates. The sheaves in each block are threaded on the same

spindle and can rotate independently of each other. In every case where the number of sheaves in the upper block is the same as in the lower block, the cord will be secured to the upper block, and the cords will be of an even number; whereas, when the number of sheaves in the lower block is one less than in the upper block, the cord will be secured to the lower block and the ropes will be of an odd number.
Take the case of a pulley block tackle with three sheaves in the top and in the lower block (see Fig. 13). The cord is secured to the upper block, then passes under one of the sheaves of the lower block, then upwards over a sheave of the upper block, then downwards under a second sheave of the lower block, and so on, P being applied to the free end of the cord, which is spoken of as the fall. It will be seen that there are six cords supporting the weight W, and as the tension on each of the cords = P, $W = 6P$, $P = \frac{W}{6}$ and P's motion = 6 W's motion.
Weston's Differential Pulley Block.—In the rope and pulley block the mechanical advantage is limited to the number of ropes support-

ing the weight, and the amount of rope required to lift a load is N times the distance the weight moves through, N denoting the number of ropes. To obviate this we can use Weston's differential pulley block, by which a much greater mechanical advantage is obtained, besides which an endless chain is used and the length of the loose loop can be suited to any heights through which W has to be raised. In this arrangement (see Figs. 14 and 15) a compound pulley of two different diameters rotates on a spindle. The rim is recessed to suit the links of the chain, so that any movement of the chain causes a rotation of the pulley. The chain is an endless one passing over each part of the pulley, and one of the loops thus formed passes under a single movable pulley, while the other hangs loose; on the side of this loop which hangs from the larger part of the pulley, P is applied.

Let R equal the larger radius and r the

weight moves through 1ft., and then measure the number of feet the chain has moved through. The result will be the velocity ratio of P to W . Next, having a known weight W fixed in the hook of the block, apply a power fixed on the chain, say a spring balance, until it is just sufficient to move the weight. Then $W \times \text{1ft.} = \text{the work done on } W$ while moving through 1ft., and the work done by $P = \text{the weight shown by spring balance} \times \text{velocity ratio}$. Then the work done in overcoming friction for every foot of lift = work done by P minus the work done on W , which will be found to be very much greater than that done on W , showing that more than half the power is lost by, or in overcoming, friction. The weight of the lower block must be added to the known weight hanging from it. I have not had an opportunity to test this data. Example to show mechanical advantage: Diameters of parts of compound sheave 6in.

smaller radius. The tension on each part of the chain supporting the lower block is $\frac{W}{2}$. Suppose the compound pulley to make one revolution, the motion of P will be $2\pi R$, and its work will be $P \times 2\pi R$, and the motion of W in the same time will be $\frac{2\pi R - 2\pi r}{2}$;

because when the pull is applied the cord is wound on the larger diameter and unwound from the smaller one, and as W is supported by two cords, the distance that it is raised in a given time is equal to half the difference between the length coiled on the one and that uncoiled from the other. W 's work will be $W\pi(R-r)$; but P 's work and W 's work are equal, as there is equilibrium $\therefore P \times 2\pi R = W\pi(R-r)$, or $P \times 2R = W(R-r)$

$\therefore P = \frac{W}{2R}(R-r)$ and $W = \frac{2PR}{R-r}$, or the mechanical advantage = $\frac{2R}{R-r}$.

From the equation for the mechanical advantage it will be seen that there is no limit theoretically to the W that can be supported by a given P , as the difference between the diameters of the parts of a compound pulley can be made as small as we please.

Now, it is well known that in this pulley block the weight remains suspended after the pull has been removed, and the question naturally arises, how is this? The reason is that more than half of the power exerted is lost by friction, or in other words, the efficiency of the apparatus is less than $\frac{1}{2}$.

The actual efficiency could be determined by experiment. First, by finding the velocity ratio. To do this, mark on a rod or stick the position of P and W . Pull the chain until the

and $\frac{1}{2}$ in. Find what W would be supported by a P of 30lbs. $W = \frac{2PR}{R-r} = \frac{30 \times 3 \times 2}{3 - 2\frac{1}{2}} = \frac{180}{\frac{1}{2}} = 360$ or $W = 720$ lbs. Practically, this would be less than 360lbs.

It will be understood also that, to lower the weight, that part of the loop which comes from the small diameter must be pulled.

The foregoing mechanical arrangements are all for the purpose of raising loads any considerable distance, and are limited only by the length of the rope or chain available. None of these, however, would be suitable for shoring, under-pinning of walls, or anything that is required to be held in position until it is made good by masonry, brickwork, or otherwise. This will be considered in the next article.

(To be concluded.)

London County Council.—At last week's meeting the Housing of the Working Classes Committee reported the approaching completion of the last of the twenty-three blocks of dwellings which have been erected upon the Boundary Street estate, at an outlay of £633,000, and stated that the Prince of Wales had consented to perform the opening ceremony on March 3rd. The chairman of the General Purposes Committee was asked whether he would consider the desirability of sending a proposal to the Technical Education Board that they should vote a sum of money by which skilled London artisans might be sent to the Paris Exhibition, as had been done by the City Corporation in the case of the last Paris Exhibition. Mr. Strong said that the matter should be brought before the committee.

Builders' Notes.

A Case about Internal Soil Pipes.—In the case of *Mair v. the Local Authority of the District of the Lower Ward of Lancashire*, heard recently at Glasgow, the respondent contested the power of the local authority to enforce a regulation requiring written explanations to be lodged in cases where internal soil and waste pipes were necessary in buildings proposed to be erected. On August 7th, 1899, the district committee confirmed a recommendation of a sub-committee requiring written explanations, with plans, to be lodged with them where it was not practicable to carry the waste and soil pipes outside. Respondent refused to comply with this regulation, and proceeded on August 28th to build. Action was then taken against him. Sheriff Boyd was of opinion that the course adopted by the respondent was not his proper remedy in raising the question as to the local authority's right to impose their new regulation, and that he thus laid himself open to the attack made upon him. In finding respondent technically guilty, the Sheriff stated that he thought it was clear that this error on the part of the respondent was provoked by the mistake of the local authority. He imposed a penalty of one shilling for building without approval, and one shilling for continuing to build, and one shilling for building without notice, allowing expenses to neither party.

Omissions in Estimates.—In the Scottish Court of Sessions recently, Robert Mitchell, an Aberdeen builder, appealed against a decision by the Sheriff of Aberdeen in an action in which he (Mitchell) was sued by the Senton Brick and Tile Company for payment of £226. The plaintiffs were erecting a brickworks, and the defendant offered to execute the carpenter work for £859, which offer was accepted. It appeared that in pricing the schedule of estimates, the defendant's son innocently and erroneously omitted to charge for 1,154 yds. super. of galvanised corrugated iron, valued at £110 11s. 10d., and that he also omitted to transfer to his notebook certain summations amounting to £215 13s. 6d. In consequence of these omissions the defendant thought he was justified in refusing to implement the contract, and the plaintiffs had to enter into a contract with another contractor for the execution of the work. Sheriff Crawford held that the error was not a clerical error; that the offer and acceptance constituted a valid and binding contract for the execution of the work for a lump sum, and had no reference to the schedule of prices to be prepared by the defendant; and that the error did not entitle the defendant to be relieved from the obligations of the contract. The Sheriff therefore decreed in terms of the conclusions of the summons. The Court of Session adhered to this decision, but thought £40 was ample to cover the loss sustained by the plaintiffs, who were also awarded expenses.

Tipping Rubbish on Land: an Interesting Case.—On Wednesday last, in the Chancery Division of the High Court of Justice, the case of the *West Ham Central Charity Board v. the East London Waterworks Company and Base* (an under-tenant) was heard. The plaintiffs wanted an injunction to stop the defendants putting rubbish, earth or material on certain land. This land had been demised in 1830 to the waterworks company for forming a reservoir; but the company never did this, and, in 1896, let the land to one Base, who used it as a rubbish shoot, and deposited on it vegetable and other refuse. The plaintiffs alleged that this user of the land was a damage to the reversion. On the other hand evidence was adduced to show that the value of the land was materially increased. Mr. Justice Buckley said that it was clear that the authority given by the waterworks company to the defendant Base was to level up the land, but that authority did not extend to allowing him to bring offensive material on the land. It was contended that the vegetable refuse would disappear in about three years. But if it did not the plaintiffs

might find themselves at the termination of the lease precluded by section 25 of the Public Health Acts Amendment Act, 1890, from building upon the land. It was admitted by both sides that the land would, in the future, be used for the erection of factories and not of houses. The defendant Base had raised the land 10ft. above its original level. If this were left it would be necessary, in building factories or other heavy buildings, to dig through this 10ft. down to the original land before a good foundation could be obtained. The question was whether this constituted an alteration of the property demised. The defendants contended that it was not, and that, although it would be necessary to dig down through the 10ft., yet the extra cost incurred in so doing would be more than recouped by the additional value attaching to the raised land. His Lordship did not agree. In his opinion the raising of the land constituted waste. The reversioners might wish to let the property for a rubbish shoot, but by the alteration of the level the inheritance would lose the benefit of doing so. Why should they not have the property restored to them in its original state? In his Lordship's opinion, there had been such an alteration of the level of the property as to constitute waste, and the plaintiffs were entitled against both the defendants to the injunction they asked.

Crystal Palace Stables Case.—On February 7th, in the Queen's Bench Division of the High Court of Justice, the appeal case stated from Justices of London of the *Crystal Palace Company v. London County Council* was heard. The company was charged with erecting at the grounds of the Crystal Palace certain buildings to which Part 7 of the London Building Act, 1894, applied—to wit, a 22-stall stable, a loose-box, stabling, and harness-room, a forage store, and office, and a shoeing forge—without having obtained the approval of the Council. The stables and other buildings in respect of which the information was preferred were erected in May and June, 1899, for use in connection with land laid out by the appellants as a polo-ground. The buildings were situated about a quarter of a mile from the main building. By section 21 of the Crystal Palace Act, 1881, it was provided that "the main building, conservatories, and waterworks of the company, and the conveniences and other works immediately connected therewith, shall be exempted from the operation of Part 1 of the Metropolitan Building Act, 1855, and of any other Act amending the same, but this exemption shall not extend to any dwelling-house or building as aforesaid upon any part of the property of the company." The Metropolitan Building Act, 1855, was repealed by the London Building Act, 1894, but by section 218 it is provided that where in any Act or document the provisions of the Act of 1855 are referred to, such Act or document shall, with the necessary modification, be read as if the corresponding provisions of the Act of 1894 were therein mentioned, instead of the provisions of the repealed Act. The Justices convicted the appellants.—Mr. Freeman, Q.C., contended that the stables were exempted from the provisions of the London Building Act by virtue of section 21 of the Crystal Palace Act, because they were "immediately connected" with the objects for which the Crystal Palace was re-erected and the grounds laid out, which included the amusement and elevation of the people.—The Court dismissed the appeal. Mr. Justice Channell said that "works immediately connected therewith" meant works connected with the main building—that was to say, the physical structure, not the objects of the appellant company. The polo-pony stables being a quarter of a mile away from the main building were not connected with it in the sense intended in the Crystal Palace Act, and were, accordingly, not exempted from the provisions of the London Building Act. Mr. Justice Bucknill concurred.

For Electrical Extensions at Blackburn the Town Council has resolved to borrow £220,000.

Engineering Notes.

Manchester City Gas Engineer.—Mr. J. G. Newbigging has been appointed engineer to the Gas Committee of the Corporation of Manchester.

Automatic Gas Meters.—During the past twelve months 75,258,000 pennies, weighing 647 tons, were dropped into the automatic penny-in-the-slot gas meters supplied by the Gas Light and Coke Company to 114,668 consumers.

Electric Light at Sheffield.—Tasker's Engineering Company, Sheffield, have secured a large contract for extensions of the plant at the Sheffield electric light station. The contract is for supplying and fixing a 1,500 horsepower condenser and large steam and water mains.

Municipal Socialism.—The Electricity Committee of the Halifax Town Council has decided, subject to the approval of the Council, to grant a bonus to members of the staff employed at the electricity works on the total works and management costs when these are brought below 1.5 pence per unit.

The New Bradford Tramways.—The Tramways Committee of the Bradford City Council recommended the Council to accept the tender of Macartney, McElroy and Co., Limited, for the complete electrical overhead equipment of the Lister Hills, Stanningley, Whetley Hill, and Thornton tramway sections for £12,064. 15s. 2d.

Water Mains and Electrolysis.—At last week's meeting of the Manchester City Council a long discussion took place with regard to the allegation that the water mains were being damaged by electrolysis; it was eventually decided to have an expert report presented to the Council on the matter.

Acetylene.—After the expiration of forty days from February 6th last it is proposed to submit to her Majesty in Council the draft of an Order in Council providing that acetylene, when in admixture with atmospheric air, or with oxygen, shall be deemed to be an explosive within the meaning of the Explosive Act, 1875, and that it shall not be manufactured, imported, kept, conveyed, or sold. Notice is also given that, in accordance with the Rules Publication Act, 1893, copies of the proposed draft Order in Council may be obtained by any public body, within the period of forty days, at the Privy Council Office, Whitehall.

Proposed Pier at Dawlish.—The pier which it is proposed to erect at Dawlish will be built on cast-iron piles, braced with wrought-iron tie-rods, the deck being of timber. The landing stage at the end will be carried on green-heart piles, driven into the sea bed and braced with timber, with provision for high-water landing and low-water steps for small boats. Seats will be provided at intervals along the deck of the pier, which will be lighted by gas. Steamers from Torquay will be able to land passengers at all states of the tide, except during exceptionally low spring tides, which occur about twice a month. The cost of construction is estimated at nearly £5,000.

New Bridge at Tranmere.—The old bridge of the Joint Railway line running over the Green Lane Railway at Tranmere has recently been taken away and a new bridge substituted. The new steel girder bridge is of 60ft. span, with a width of 30ft., the entire weight being about 80 tons. This had been constructed on the west side of the line on rollers, and was moved into its place and fixed in a very brief period, the supporting walls having been previously erected to the required height. Messrs. Gabbatt, contractors, Liverpool, carried out the practical portion of the work, the structure being furnished by the Dalham Forge Company, of Warrington.

The Floor System of Girder Bridges was dealt with by Mr. C. F. Findlay, M.A., M.I.C.E., at a meeting of the Institution of Civil Engineers held last week. He considered that the advantages claimed for simple triangulated types of construction, in respect of the more definite determination of stress

which they permit, had been much exaggerated, and that there were many cases in which the lattice-girder was the most suitable type to use, having regard to economy, practical convenience, and appearance. When lattice-girders were used a comparatively close spacing of cross-girders often became imperative.

Masters and Men.

The Bristol Master Builders' Association held their annual dinner last Wednesday.

The Operative Plumbers of Hull have been granted an increase of a halfpenny per hour by the masters, to date from April 13th next.

The Kirkcaldy Operative Masons have agreed to accept the master builders' terms, namely a reduction of a halfpenny per hour which will make the wage 8½d. per hour. This agreement is to hold good between masters and men until May 31st, 1901.

Dundee Joiners' Dispute Settled.—At a meeting of the Dundee Joiners' Conciliation Board held last Wednesday, the various points in dispute in connection with the drawing up of the working bye-laws for the year were amicably settled. The employers desired to be allowed to revert to the old arrangement whereby they would be called upon to pay the standard rate of wages only to "competent" men. Several years ago the men held out against the continuance of this system, and after negotiation gained their point. They refused to sign the rules this year if the word "competent" were again introduced, and last week the masters agreed not to press the point, and to pay the standard rate to all men.

Newport (Mon.) Building Trade Dispute, after enduring for nearly seven months, was settled last Saturday week. An agreement was signed embodying a code of working rules to last for five years, the question of the rise or fall of wages being subject to six months' notice given on November 1st in any year. The men return to work at 8½d. per hour, or an advance of a halfpenny; but this rise the masters—it is alleged on their behalf—were willing to give when the men came out in July last. The members of the Newport branches of the Associated Society of Carpenters and Joiners signed the code of rules and agreement as to wages on the Monday. The masters have also decided to accept the new terms, and it is stated that the dispute with the labourers is in a fair way of being settled, the men having withdrawn the demand for a farthing which is in dispute, and have asked for a written guarantee that the question be reconsidered when an increase is conceded to labourers in Cardiff and Bristol. The plasterers are still holding out upon the question of their right to refuse to work with non-unionists, which, they state, was conceded by the Federation in the settlement of the national dispute.

Halifax Borough Engineer and Surveyorship.—For the post of borough engineer and surveyor under the Halifax Corporation, for which a salary of £500 a year was offered, there have been fifty seven candidates. Mr. James Lord, deputy borough and waterworks engineer, Blackburn, has been appointed.

Sanitation at Gainsborough.—A special committee of the Gainsborough Urban Council has considered and reported upon Dr. Darra Mair's inquiry into the sanitary condition of the town. They point out that they are taking steps to close certain condemned slum property; to concrete the foundations of all new houses, as required by the by-laws; and to establish a more regular inspection of new buildings with a view to preventing "jerry" building. The question of sewage disposal has also been tackled, and the old obnoxious vault system done away with. The surveyor was also engaged in preparing plans of the sewers and outfalls into the Trent.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.	WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDER MAY BE OBTAINED.
BUILDING—			
Feb. 16	Luton—Buildings	School Board	J. E. Brown and Son, Castle-street, Luton.

Messrs. FAREBROTHER, ELLIS, and CO. publish in the advertisement columns of "The Times," "Standard," and "Morning Post," every Saturday a list of their forthcoming Sales by Auction. They also issue on the first of every month a schedule of properties to be let or sold, comprising landed and residential estates, farms, freehold and leasehold houses, City offices and warehouses, ground-rents, and investments generally, which will be forwarded free of charge on application.—No. 29, Fleet-street, Temple Bar, and 18, Old Broad-street, E.C.

A MAGNIFICENT FREEHOLD, RESIDENTIAL and BUILDING ESTATE for DISPOSAL, situate five minutes from a station, in a favourite position, only thirty-five minutes from town, and having extensive main road frontages; the well-timbered park lands of over fifty acres; are immediately available for independent development, and can now be obtained at a low price of £250 per acre, and will be worth double in the course of a few years. The mansion and stabling and very extensive grounds are in first-class order for immediate occupation, boating, fishing, and golf are near at hand, and the acquisition of this property presents an opportunity for residence, combined with profitable investment, seldom to be met with.

Full detailed particulars and plan will be forwarded to intending purchasers or their solicitors by the Owner's Agents, Messrs. GEORGE TROLLOPE and SONS, 4, Mount-street, W.

R. I. B. A. EXAMS. PREPARATION, personally or by correspondence, in three, six, nine, or twelve months' courses. Architectural and Library. Special three months' finishing courses.—For full particulars apply to Messrs. LOWGATE and BOND, Associates R. I. B. A., 115, Tottenham-street, W.C. (close to the British Museum).

MODELS.

For Exhibitions or Law Cases. Illustrations sent of Work Executed. JOHN B. THORP, 98, Gray's Inn-road, W.C.

R. I. B. A., Society of Architects, and Civil Service Technical Examinations. Personal, correspondence, or resident preparation. Seventeen first places.—MIDDLETON and CARDEN, Associates R. I. B. A., 19, Craven-street, W.C.

APPOINTMENTS VACANT.

ARCHITECT'S ASSISTANT (competent) WANTED.—Write, stating age, experience, and salary required to CARTER and ASHWORTH, Architects, 86, Eden-street, Kingston-on-Thames.

EFFINGHAM HOUSE,
ARUNDEL STREET,
STRAND, W.C.

THE BUILDERS' JOURNAL SHILLING FUND (see page 35) has been started to assist in the erection of Homes for Discharged Soldiers at Bisley. This is the Building Trades' Gift to the Nation, and every patriotic reader of the **BUILDERS' JOURNAL** should share in it.

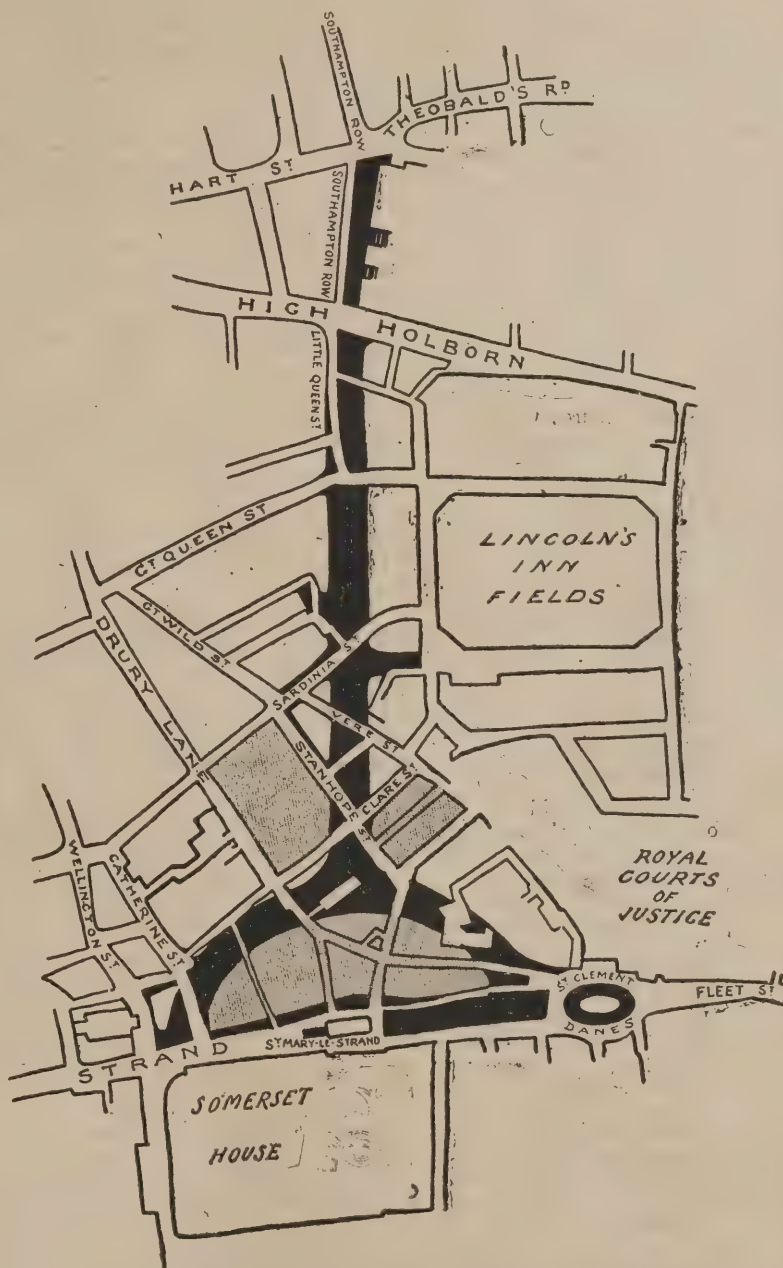

An Architectural Causerie.

The New Street. THREATENED houses, equally with threatened men, live long. It is nine years since the project for a new thoroughfare from Holborn to the Strand first began to take shape, and not yet has a single house along the line of this great metropolitan improvement been demolished. Now, however, after many false reports, we really seem to be on the eve of a beginning, and the hundred times threatened Holywell Street may count its last days without much effort. For here will the first step be taken, somewhat in advance of the works along the line mapped out north and south. This is in deference to the urgency of the demand for a widening of the Strand at this point, which the demolition of the houses on the north side of the Strand and the south side of Holywell Street will at once give. The property is already in the Council's hands, and it is not likely to be many weeks before the houses are cleared of their tenants and on the road to destruction. Unhonoured, if not altogether unsung, this thoroughfare of a thoroughly reputable nomenclature and an utterly disreputable savour, will thus disappear from the map of London. Not altogether wanting in elements of the picturesque, Holywell Street derives its real name from a "holy well" which is said to have existed here; and its pseudonym of "Booksellers' Row" from the vendors of literature of all sorts, new and second-hand, who crowd together in this narrow way. Wych Street, and with it both the Globe and the Opera Comique Theatres, will closely follow upon the disappearance of Holywell Street. Here also some Elizabethan houses of many and overhanging storeys, picturesquely grimy and hump-backed, will be lost to the artist and will cease to afford a text for the sanitarian. Among them is a double-gabled building of timber and plaster, which was "restored" in a small way two years ago, and is traditionally said to have been the home of the carpenter to whom that bright spirit of his times, the redoubtable Jack Sheppard, was apprenticed. It was at the back of this house, and in the yard of a house in Holywell Street, that, according to the late George Augustus Sala, the ancient "holy well" was re-discovered, about fifty years ago. Inappropriately enough, it was on the premises of what was then a public-house. Sala was present at the exploration of the dried-up well-shaft, and he says that expectations of archaeological finds were great. Those hopes, however, were doomed to dis-

appointment, for old boots, oyster shells, broken crockery, and two battered coins were the sole treasures that rewarded the explorers. One coin, which proved to be a halfpenny of George the Fourth's reign, sufficiently proved, if the other "finds" did not, that they had not lighted upon mediæval relics.

We have dwelt rather upon this corner of the forthcoming improvements because it happens that this is the oldest district to be cleared, and the most interesting. This portion will cost £162,000. The sketch map printed herewith will clearly show the property to be acquired and demolished along

hope, Vere, and Sardinia Streets, through which the new thoroughfare will cut, bear honoured names, smirched—long years since by the degradation into which the purlieus of Drury Lane and Clare Market have fallen, so that it is difficult to realise that this was once a fashionable centre, and that "pretty Mistress Gwynne" did not disdain residence hereabouts. It is here that the County Council has an additional improvement on hand which has nothing to do with the new street scheme, but will result in clearing away once for all the slums of Clare Market, Holles Street, Clare Street, and the great

THE NEW HOLBORN TO STRAND THOROUGHFARE: PLAN SHOWING PROPERTY TO BE DEMOLISHED.

The thick black line marks line of street and property to be acquired for it. Dotted spaces indicate areas to be cleared under powers acquired and to be re-built.

the whole course of the improvement. Four theatres will disappear—the Olympic, Gaiety, Opera Comique, and Globe—but they will doubtless be rebuilt on other sites and in greatly improved form; nor in the destruction of any one of the present buildings need there be anything to regret, for even the Gaiety, built though it was only some twenty-five years ago, scarcely realizes the modern idea of a thoroughly efficient theatre, while the others are utterly indefensible from whatever point of view they may be regarded—whether of safety or convenience. Stan-

insanitary area bounded by Kemble Street, Drury Lane, Blackmoor Street, and Stanhope Street. These areas have been cleared under the provisions of the Housing of the Working Classes Act of 1890, at a cost, as estimated, of £216,000. Past them and across dingy Sardinia Street, the course of the new thoroughfare butts up against the works of the Electric Light Corporation, which will have to be removed and rebuilt on another site. Thence the way lies through a dense mass of alleys and factories, and larger or smaller business premises, to

Great Queen Street, which will be crossed, and the line of Little Queen Street, followed to High Holborn and Southampton Row. Little Queen Street will be widened on its east side and slightly at the south end of the west side also. The Southampton Row widening, already undertaken as far as it is intended to go—that is to say, to a junction with Theobald's Road—costs £162,000. The total cost of these huge works will entirely throw into the shade anything hitherto done in the way of metropolitan street improvements. The Metropolitan Board of Works in the thirty-three years of its existence spent £11,500,000, or £348,000 per annum; but this scheme alone will give a total cost for land acquired of £4,442,400. Recoupment, it is estimated will bring back the whole of this sum with the exception of £354,100. Additional expenditure for providing accommodation for the rehousing of the working class will amount to £300,000, bringing the final cost to £774,100.

C. G. H.

Art for All.* THE cheapness with which books may be illustrated no longer excites surprise. The process block, like the bicycle, is a thing which has come to stay, and a block as we know is simply so much type; it forms an integral part of the page, and sheets may be filled with reproductions of Rembrandt's works as cheaply as they could be with what may be written about them. Mr. Knackfuss, the author, is probably pleased to see his monograph done into English, and advised not to expect very much as his share. There remains the translator—what is earned by a lady-help in an indigent family compares favourably with his reward. The book which suggests these remarks is only one of some hundreds which have appeared in the course of the last few years having this characteristic in common—neither author nor artist is paid. It may be thought that I am complaining, but that is far indeed from my purpose, for there is no other way of extending to all the advantages of education in art, and it should be generally known how such really good things are produced. The translation of M. Michel's great work in two volumes which appeared some years ago was only for those who could afford it, and what we have here is a volume which contains in compact form, leaving little to be desired, an account of the man's life and work as able as any so far as I know, and in some respects more complete. Not elsewhere, I believe (not in English at least), will be found the author's rescript of the "inventory of the master's movable property," taken in 1656 by the officers of the Bankruptcy Court with a view to a public auction; a melancholy document this is indeed, and I should be sorry to have to quote it at length, but interesting to us as it proves that Rembrandt was by no means so blind to beauty as one might be led to suppose by the creatures who figure in his representations of sacred and classical subjects. In fact, the eclectic spirit of the collector was his in a large degree, and Amsterdam, the chief port of the world, was exactly the place for him. In the multi-coloured robes of the Jews he delighted, and in the queerest Japanese gawds, things quite the reverse of beautiful, but marvels of art notwithstanding. As his collection of prints included examples of all the Italian schools, he had many examples of beauty before him, and clearly it was of set purpose that he painted always according to Nature—Dutch nature. That beauty is one of the Devil's snares is not denied even now, and the artists of Rembrandt's age had not only this to avoid, but the idolatry, as they would have called it, of that form of religion which the Inquisition had made so hateful. E. R.

* "Rembrandt." By H. Knackfuss; translated by Campbell Dodgson. London: H. Grevel and Co. 4s.

On Reflection.

Ruskin and the Royal Gold Medal.

THE last number of the "Journal of the Royal Institute of British Architects" contains three very interesting letters from John Ruskin, which, although written in 1874, have not hitherto been published. In that year the gold medal given annually by the Queen was adjudged by the Institute to Ruskin. The Institute honoured itself in its choice, and we can well believe that neither before nor since has the distinction been more worthily bestowed. The Institute, however, reckoned without Ruskin—always an unsafe thing to do; and we can imagine the consternation with which the secretary received one fine morning in May, Ruskin's reply to the letter, advising him of the honour it was proposed to confer on him. The reply was a courteous but firm refusal to accept the medal, and an explanation of the reasons which led him to take such an attitude. The reasons were briefly that architecture had fallen on evil days, acts of Vandalism were perpetrated on every hand (the letter quoted four typical examples), under the name of restoration the most celebrated works were being destroyed for the sake of emolument, and for all this the Institute was responsible. "Under these circumstances," the letter continued, "I cannot but feel that it is no time for us to play at adjudging medals to each other, and must, for my own poor part, very solemnly decline concurrence in such complimentary formalities, whether as they regard others or myself. For we have none of us, it seems to me, any right remaining either to bestow or to receive honours, and least of all those which proceed from the grace and involve the dignity of the British throne." This letter, although obviously written for communication to the Institute as a whole, was suppressed by the Council of that day, for what reasons we are left to conjecture. Possibly they felt that the knowledge that they had received such a rebuff would lessen the sense of veneration in which junior members of the profession ought to hold those "potent, grave, and reverend seigneurs," the Council of the R.I.B.A.; or, possibly they were conscious that the "Master" had expressed with his accustomed directness and force certain home truths which they would have preferred should remain unspoken. However this may be, the action they took in the matter seems to have been to commission the president, Sir Gilbert Scott, to remonstrate with Ruskin and seek to alter his decision.

Plain Speaking to the R.I.B.A.

THE effect of the President's communication was to call forth a second letter, in which Ruskin expressed with even greater vehemence his poor opinion of architects in general and the R.I.B.A. in particular. "I very solemnly deny," he wrote, . . . "that either the Architects' Institute or any other dominant association of artists in England, France, or Italy, is, or can be in the present day, an association for the improvement of architecture, or of any other art by such dominant associations professed. The primary object of all such associations is to exalt the power of their own profession over the mind of the public, power being in the present century synonymous with wealth. And the root of all the evil and ruin which this century has seen . . . is summed up in four words, 'Commission on the cost.' And from any body of architects, however small, who will bind themselves henceforward to accept a given salary (whatever amount according to their standard they may choose to name)

for their daily work, and to work with their men (or, at least, with their own hands, on the sculpture of the building) while they take such salary—from such a body I will take a medal to-morrow." He goes on to speak of the scornful opposition he has met in every effort he ever made which came into collision with the pecuniary interests of modern builders, and quoting a remark of Sir Gilbert Scott's that "the public as a body scarcely know the difference between good architecture and bad," he asks "as a body does the Institute? If it does, why has it not taught the public? If it does not, shall I take the medal, implying the recognition of its authority?" The third letter is unimportant—or should we say it is most important of all as showing the kindly feeling that with all his prophetic ire Ruskin ever entertained towards his friends, even when they disagreed with him? It is simply a private note explaining to Sir Gilbert Scott that the letter he enclosed was written under unusual irritation caused by witnessing the destruction of one of the loveliest scenes in Italy. "I hope" he writes "I have said nothing more than is right (at least in my view) in consequence of this irritation. But I can only say that if I wrote, or could write, as I feel, any day of my life, you would pity me not be angry with me."

Covent Garden "Piazza."

ALTHOUGH the word Piazza only means a place, and is currently

applied in Italy to almost every open space surrounded by houses, it has in London been given a limited and special meaning, that of a square with covered arcaded pavements, whilst popular custom has of late years still further narrowed it to the north side of a single square. Covent Garden was originally designed by Inigo Jones and was intended strictly to follow the lines of the arcaded squares of Leghorn or Livorno where the architect had long resided. He was the first to deliberately introduce the complete Italian Renaissance into England, not the details only as in the Elizabethan buildings but the entire system. "Covent" or Convent Garden, originally the property of the abbey of Westminster, was intended to be fully surrounded with arcades; this, however, was never done; only the north and north-eastern pavements were covered over, and of these but one remains entire. It is in four storeys, the lowest being arcaded; the whole is beautifully proportioned. A spectator with his back to the market, and looking up York Street towards Long Acre, cannot fail to notice the delicacy of outline of the eastern block, which is Inigo's work, and, unfortunately, all that remains of it. In the rebuilding of the western one his scale and proportions have been completely disregarded; the height is greater and alterations have been made in other parts of the square. Covent Garden is now scarcely to be recognised. Covered walks of this kind were again used long afterwards by Nash in Pall Mall East and one or two other places; the former has been removed in building the new Carlton Hotel. Another, of a different design, was pulled down in Regent Street in 1848, and in each case there has been a distinct loss of picturesque effect to London. If it be contended that such structures are dark, the answer is ready that with our improved illuminants they could easily be made light, and in any case would be of the greatest use to the public in wet weather. Covent Garden is always a favourite place with Londoners on account of its charming little avenue filled with flowers and fruit which runs through the market buildings; it is not many of them, however, that notice its roof and method of lighting, which curiously resemble those of a simple basilica.

"BUILDERS' JOURNAL" SHILLING FUND.

AN OFFER TO COLLECTORS.

A SPECIALLY gratifying feature in connection with our Shilling Fund has been the way in which many of our readers have made use of the collecting forms we issued to obtain subscriptions from their friends or fellow workers. We feel convinced that a great deal more might be done in this way, as there must be many thousands in builders' workshops and architects' offices throughout the country who would willingly give a small donation to such a worthy cause if a personal request were made to them, though possibly they would not take the trouble to send off a contribution on their own account. In order to encourage those who have begun to collect and to enlist the services of many fresh collectors, we have decided to present a copy of the latest issue of "Specification" to every contributor or collector of twenty shillings and upwards. "Specification" is becoming more and more widely known as an invaluable book of reference for architects and builders; it is published at 5s. nett, and contains a vast amount of conveniently arranged and thoroughly reliable information on an immense variety of subjects relating to architectural and building practice. This offer applies equally to those who have already sent in their contributions; if they wish for a copy of "Specification" to be sent to them, will they kindly send us word to that effect? Donors of smaller sums than twenty shillings may, of course, make themselves eligible for this gift by sending in the amount of the difference.

We hold over until next week the list of contributions received for our Shilling Fund since we went to press last week, and publish this week a full list of the contributions in kind which had been received up to Saturday last at the Offices of the Executive of the Building Trades' Gift.

FOR THE WHOLE OF THE BUILDINGS:

Messrs. Acton and Borman.—The whole of the Glass Paper.
Messrs. D. Anderson and Son, and J. C. Broadbent and Co. (jointly).—The whole of the Slag Wool.
Messrs. Robert Boyle and Son.—The entire natural Ventilation Appliances for the whole of the buildings.
Messrs. Carter and Aynesley.—The entire Locks.
Messrs. S. and E. Collier (Reading).—The entire Ridge Tiles.
Messrs. Diespeker and Co.—The entire Mosaic Flooring for Lobbies, Halls, Lavatories, &c.
Messrs. T. and W. Farmiloe.—The entire Whitelead, Colour, Oils, Turps, Varnish, Brushes, and Paint Pots.
Messrs. Hobbs, Hart and Co.—The entire Locks.
Messrs. G. B. Kent and Sons.—Paint, Toilet, and various Brushes.
Messrs. Nicholls and Clarke.—The whole of the Glazing.
Messrs. T. Rider and Sons.—The Dressers for the whole of the Homes.
Messrs. John Roberts and Son (Leeds).—The whole of the Nails for the Roof.
Messrs. Roberts, Adlard and Co.—The laying of the entire Slatting (exclusive of slates).
The Velocog Slate and Marble Quarries.—The entire Damp Course Slates, Slate Shelves, Slabs, &c.
Messrs. Webb's Engineering Co. (Birmingham).—The entire Door Fittings and Window Furniture, and the General Ironmongery and Taps.
Messrs. G. A. Williams and Son.—The whole of the Interior Blinds.
Messrs. Doulton and Co.—2,000ft. of Drain Pipes, and Yard Gullies for the Six Homes.
Mr. James Brown.—Moulded Bricks and Ornamental Panels of the whole of the buildings.
Messrs. G. Tucker and Son (Loughborough).—Chimney Pots for all six Homes.
Messrs. Eastwood and Co., Limited.—750,000 Stock Bricks for the whole of the buildings.
Messrs. Pilkington and Co.—Asphalte Paving under floors throughout.
Messrs. Craven, Dunnill, and Co. (Jackfield, Shropshire).—Mosaic flooring for halls in all six homes.

FOR SPECIAL SECTIONS OF THE WORK.

The Asbestos and Asbestic Co.—Asbestic Plaster.
Messrs. G. Aston and Sons.—50cwt. of Ironwork and some Large Girders.
The B. and S. Folding Gate Co.—Indiarubber Flooring for two Bathrooms.
Messrs. Benham and Sons.—Two large Kitchen Ranges.
The Birmingham Blind Co.—A set of Outside Blinds for one Home.
Messrs. John Burton and Co.—10,000ft. run of 4in. by 2in. Batten and Ceiling Joists.
Mr. Jas. Carmichael.—Six Front Doors and Frames.
Messrs. Colls and Sons.—The complete set of forty Doors for one Home.
The Columbian Fire-Proofing Co.—The Construction of the First Floor of One Home.
The Conduit Insulation Co.—Electric Conduits.
Mr. J. F. Ebner.—Pitch Pine Flooring for the Ground Floor of Three Homes.

Messrs. J. C. Edwards (Ruabon).—9,000 Red Pressed 6in. by 6in. Flooring Quarries.
The Expanded Metal Co.—Metal Lathing for exterior walls, floors, and partitions of the Recreation House.
Mr. E. Marshal Fox (for the British and London Non-Flammable Wood Companies).—Non-Flammable Wood Joinery and Interior Timber Work for the Recreation House.
Messrs. Alfred Goslett and Co.—Three large Kitchen Ranges with high-pressure boilers.
Messrs. Thos. Gregory and Co.—Wood-block Flooring for the Recreation Hall.
Messrs. Hilton, Anderson, Brooks and Co.—50 tons of Portland Cement.
Messrs. Hollis Bros. (Leicester).—The Architraves for one Home.
Messrs. Humphreys.—A 30ft. Iron Building for Workshops.
Messrs. Kirk and Randall.—75 squares of Lin. Roof Boarding.
Messrs. Lander and Co.—The Warm Air Grates for the Recreation House.
Messrs. Thos. Lawrence and Sons (Bracknell, Berks.).—25,000 Red facing bricks, and 500ft. of molded bricks.
Messrs. Wm. Lee; Son and Co.—25 tons of Portland Cement and 50 yards of Lime.
Messrs. Lindsay, Neal and Co.—The Heavy Girders for a Pair of Homes.
Mr. E. Lucas.—A Service Lift.
Messrs. Macevoy and Holt (North Fleet).—50 tons Cement.
Messrs. McNeil and Co.—The Slag Wool and Roof Felting for one Home.
The Mural Decoration Syndicate.—50yds. of Partitions.
Messrs. John Newton and Co.—The Roof Felting and the "Plasterers' Hair" for three Homes.
Lord Penrhyn (Penrhyn Quarries).—10,000 Slates.
Mr. Ashteton Smith (Dinorwic Quarries).—10,000 Slates.
Messrs. Strode and Co.—The Electric Fittings for one Home.
The Towny Company, Ltd. (Birmingham).—Twenty-five Enamel Slate Mantelpieces.
Messrs. Geo. Trollope and Sons.—Doors, Casements, and Linings for one Home.
Messrs. Twyford.—The Sanitary Fittings for one Home.
Messrs. B. Ward and Co.—An Artificial Stone Staircase for one Home.
Mr. John P. White (Leicester).—Mantelpieces, designed by the late G. H. Morris, and Garden Seats.
Messrs. Geo. Wooliscroft and Son (Hanley).—The Roofing Tiles for one Home.
Messrs. Maw and Co. (Shropshire).—250 yards super. Tiling for paving.
Mr. George Jennings (preliminary).—Sanitary Fittings for one Home.
Moorgate Engineering Co.—Iron Staircase for Recreation House.
Mr. Jabez Thompson (Northwich, Cheshire).—1,000 Patent Brickwoods.
Mr. William Wiffen (Holsworthy, Devon).—Oak Lintels for one Home.
Darbishers' Granite Quarries (Penmaenmawr).—Some Granite for Macadam.
Messrs. Towers and Williamson (Grantham).—Clinkers for Workshops and Stable floors.
The British Uralite Co.—18,000 square feet of Uralite Slabs.
Messrs. W. H. Lorden and Son (Upper Tooting).—twelve Window Sashes and Frames.
Messrs. E. and C. Braby.—1,000 feet super. of Opal Tiling.
Messrs. Dent and Hellyer.—Sanitary Fittings for one Home.
Messrs. Stephens, Bastow and Co. (Bristol).—forty Doors.
The Sub-Wealdon Gypsum Company (Robertsbridge, Sussex).—25 tons S. rapite Plaster.
Messrs. Fredk. Braby and Co.—1,600 square feet of zinc roofing.
The Poole Steam Joinery Works (Poole).—The architrave mouldings for one Home.
Messrs. J. and F. Gridley (Woking).—The Slate battens for three Homes.
Mr. B. E. Nightingale and Workmen.—Staircase for one Home.
The Lift and Hoist Company.—A service Lift.
Messrs. Durrants' Gully Company.—Twelve Patent Road Gullies.
Messrs. J. W. Falkner and Son.—Forty Doors for one Home.
Messrs. Cartland and Sons (Birmingham).—Four sets swing centres.
Messrs. W. W. Howard Bros. and Co.—£25 worth of wood materials.
Messrs. McTeart and Co. (Belfast).—Roofing felt for three Homes.
The Festiniog District Slate Quarry Proprietors Association (Merioneth) (Per Mr. John George Ashmore).—10,000 Portmadoc Slates.
Kensington Blind Works.—Outside Blinds for one Home.
Messrs. Malcolm, Macleod and Co.—1,000ft. of granite paving.
Messrs. Burt and Potts.—Metal Casement Windows for ground floor of Recreation House.
Mr. Thomas Faldo.—Vertical Damp Course for three Service Blocks.
Messrs. Burke and Co.—Tiling for varandahs and connection corridors.
Mr. John Marsland.—Six Dwarf Cupboards.
The Patent Victoria Stone Company.—100 feet cube Victoria Stone for entry steps.
Messrs. J. W. Furse and Co. (Nottingham).—Lightning conductors for three homes.
Messrs. Burney and Co.—A cistern and a cylinder.
Mr. J. T. Brooker (Dorking).—An entrance gate.
Easily Cleaned Window Co. (Shrewsbury).—per Mr. Thos. Gregory.—Twenty sets E.C.W. patent fittings.
Messrs. Treasure and Son (Shrewsbury).—per Mr. Thos. Gregory.—Twenty windows for upper floors.
Mr. Thos. G. Lichfield.—Two chimney pieces.
Messrs. William Newman and Sons (Birmingham).—Door springs for entrances.

Messrs. J. and H. Patterson (Manchester).—Marble Tablets.
Messrs. Thomas Turner and Son.—Steps for one of the homes.
Messrs. G. H. Renton and Co.—Flooring for one home.
Messrs. Young and Marten (Stratford).—Six grates.

FOR THE ELECTRIC LIGHT INSTALLATION (per. Mr. Max Byng).

The General Electric Company.—The switchboards, cutouts, ceiling roses and switches for the whole of the buildings.
Mr. G. Braulik.—Electric light fittings and switches.
The Newton Electrical Engineering Company (Taunton).—One 12½ K.W. Dynamo.
Messrs. Rashleigh, Phipps and Co.—Labour for wiring one Home.
Messrs. T. Clark and Co.—Labour for wiring two Homes.

VARIOUS GIFTS FOR THE EQUIPMENT OF THE HOMES

Mr. B. T. Batsford.—50 Books for Library.
Messrs. Busset.—Two Armchairs.
Messrs. Mansford and Son.—Typewriting Accoutrements and Stationery.
Messrs. A. S. Wilson and Co.—Drawing Materials.
Messrs. Sprague and Co.—Lithography.
Messrs. Rich and Co.—Electrography.
Mr. B. Nienhaus.—Furniture for two rooms.
Messrs. W. Summerscales and Sons (Keighley).—Two Wringing Machines.
Messrs. William Fisher and Son (West Bromwich, Staffs.).—Seating for fifty persons.
Messrs. H. Addison and Co. (Wellington, Salop).—Seats to the value of £10.
The Ratner Safe Company.—A Safe.

In addition to the above the following contributions in money have been received:—

	£	s.	d.
The Worshipful Company of Tylers and Bricklayers	105	0	0
Mr. Robert Neil (Messrs. Robt. Neil and Son, Manchester)	100	0	0
Mr. George Parker	100	0	0

Mr. A. Chippendale (Leeds)	1	1	0
Various minor sums	0	17	6

It may be well again to explain, for the benefit of any who may not have seen our previous announcements, that the purpose of the gift is to meet as far as possible the needs, which all the patriotic funds hitherto established have to a great extent overlooked, of the permanently disabled soldier discharged from the army with a pension inadequate to supply even the barest necessities of life. It is proposed to erect and equip six cottage homes at Bisley containing in all 100 beds, and in selecting inmates preference will be given to soldiers who have at some time been connected with the building trades.

The Executive of the Building Trades Gift, whose address is 1, Waterloo Place, Pall Mall, S.W., invite offers of gifts in kind. Contributions in money, of any amount from a shilling upwards, may be sent to

(Continued from page 8, No. CCLXI.)

Animals: Natural and Fabulous.

IN the early days of heraldry, when each knight could decorate his shield with the emblems that pleased him best, many ornamented their shields with those animals most renowned for bravery. Therefore the lion, the leopard, the eagle, the wild boar, and, at a much later date, dragons and griffins were eagerly adopted as distinguishing badges. But the kings and other rulers of states in nearly every case chose one of the warrior beasts, and thus, gradually, each knight had to alter the posture, or change the colour, of his charges, that there might be no confusion between the arms of the sovereign and those of his subjects.

The lion, chosen at an early date by the kings of England, was, perhaps, the animal the most highly esteemed by heraldic authorities; it is, therefore, hardly astonishing, considering the frequent use of this charge, that the lion has a great many different postures, and has undergone many curious alterations. The lion is borne in fifteen postures:—

(1) *Rampant*, erect on its hind legs, going from sinister side to dexter, its head being in profile, and its tail erect and nearly touching its back. (2) *Rampant-gardant*, erect on its hind legs, and full-faced. (3) *Rampant-regardant*, erect on its hind legs, its head in profile looking backwards. (4) *Passant*, walking past in profile, its right front paw held up, and its tail reflexed over the back. (5) *Passant-gardant*, walking past full-face, right front leg lifted, and tail reflexed over back. (6) *Passant-regardant*, in the same position as the last two, only with its head in profile looking backwards. (7) *Stantant*, with all four paws on the ground; it is generally emblazoned full-faced. (8) *Saliant*, or in the act of springing forward; there is really but very little difference between *saliant* and *passant*, but the former has its two front legs in the air. (9) *Sejeant*, seated on its haunches, its head in profile, and front paws on the ground. (10) *Sejeant-affronté*, sitting upright, full-faced, with its front legs held straight out on either side. (11) *Couchant*, lying down, its head erect, and tail beneath it. (12) *Dormant*, with its head resting on its front paws. (13) *Coward* or *coulé*, the same posture as *stantant*, its head held rather lower, and its tail between its legs. (14) *Rampant-combatant*, two lions rampant-passant placed face to face. (15) *Rampant-addossé*, two lions rampant-passant placed back to back.

Leopard was the term formally applied to the lion passant; the term, and the animal, is now but seldom used, although sometimes

leopards' heads are borne. If the head is borne in profile with a portion of the neck it is termed a *leopard's head*, but if borne full-faced with no portion of the neck visible it is termed a *leopard's face*. Besides being borne in the above fifteen positions the lion is represented as *dismembered* when all its limbs, its head, and tail are cut off from the body; as *debruised*, a term applied to any animal which is emblazoned with an ordinary placed across its body; and *defamed*, when the poor brute is deprived of its tail. Then, again, we have two-headed lions, doubled-bodied lions, dual-tailed lions—this last is the famous Bohemian cognizance—lions with fishes' and dragons' tails, and winged lions. But the most strange form it has been made to assume is that device termed *jessant-de-lis*, in which a fleur-de-lis is made to pass through the head of a lion or leopard, the flowery part coming at the back of the head and the tails out of the mouth.

The wild-boar was one of those charges early adopted as a symbol of bravery, and was given to, or adopted by, great warriors. A young wild boar is termed a *grice*. The pig also makes its appearance on shields, but especially in continental heraldry. The old Spanish heralds made constant use of the unsightly pig in order to show their hatred for the Jews and Moors, who abhorred the unclean animal.

The horse, as might be expected, is a valued charge. It is sometimes borne completely

DRAGON.

GRIFFIN.

UNICORN.

HARPY.

eating its food is termed *vorant*; *vulned* is a term applied to an animal, or part of an animal, dripping with blood; an animal *courant* is running; *saliant*, it is about to spring forward; *incensed*, it is borne with flames issuing from its mouth and nostrils; *respecting* is applied to other animals, except lions and other beasts of prey, when they are placed face to face. A tortoise walking is said to be *gradient*. An animal is often represented as having a crown, or a wreath of flowers, or leaves, round its neck, and is then said to be *gorged*. A lion, or other animal, with its teeth, claws, and tongue of a different colour to the animal itself is said to be *armed* and *langued* of that particular tincture; the term *unguled* is used for animals with hoofs of a different colour. An animal's head cut off smoothly with the neck is said to be *couped*, but if cut off with a jagged edge, *erased*.

The eagle is the animal next in order of importance after the lion. It is either emblazoned, *displayed*, with its wings spread out; as *close*, with its wings shut; or *volant*, flying. The eagle is not unfrequently displayed with two heads.

In the early days of chivalry hawking was one of the principal pastimes of the nobility, and therefore both the hawks and the objects used in hawking were often chosen by those who had special rights of hunting over large extents of forest. Hawks often appear as *belled*, *jessed*, and *varvelled*. The *bell*, which is constantly used as a separate charge, is round, with a long slit in it; a piece of metal at the top is pierced by a hole, through which the *jess*, or leather thong, is passed, and so fastened to the leg of the hawk. *Varvels* are rings attached to the leather thongs. Hawking has contributed two other names to heraldry, the hawks *lure*, or two wings joined with a thong, to which is tied a ring; and *nowed*, a term used when the thongs are knotted.

Corbie is the heraldic name for a raven; the martin is called a *martlet*. This last has gradually been deprived of its beak and legs.

After the eagle and hawk the birds most commonly used in heraldry are the pelican, the peacock, and the cock. The *pelican* is generally borne with its wings open and placed back to back, or as if in her nest feeding her young with her own blood, flowing from a self-inflicted wound, when she is said to be *in her piety*. The *cock*, when its comb, gills, claws, and beak are of a different tincture from itself, is said to be *crested*, *jelloped*, and *armed*. Birds possessing no talons are said to be *beaked* and *membered* when their beaks and legs are of a different tincture. The *peacock* is generally borne *in its pride*, that is to say, full-faced and with its tail outspread. A bird when raising its wings preparatory to flying is said to be *rising*, if flying *volant*, and when a bird of prey is represented as devouring its food it is said to be *preying*. Sometimes a

LUCIE HAURIANT.

NAKED ARM—EMBOWED.

furnished for war, when it is called *caprisoned*; or else rearing on its hind legs, when it is termed either *effaré* or *forcené*. A spancelled horse has two of its legs fettered by a log of wood.

The rabbit is termed a *conie*; the badger a *gray*; the hedgehog an *herison*; then there are goats and goats' heads, asses and asses' heads. But nearly every animal known may be found on escutcheons.

The stag is said to be at *gaze* when it is standing still, *trippant* when passing; when its antlers are of a different tincture to that of the animal it is said to be *attired*, just the same as the lion, or other savage beast, is said to be *armed* when its claws, teeth, or beak are of a different tincture. A young stag is termed a *girl*.

Caboched is a term applied to the head of any animal when it is represented either full-faced or without a neck. Any beast of prey lying down with its head held up is said to be *couchant*, but a stag or other beast of chase in this position is said to be *lodged*; a wild beast

LION RAMPANT.

LION PASSANT-GARDANT.

LION'S HEAD—ERASED.

feather has its quill of a different tincture to itself, in which case it is emblazoned as *quilled* of such a tincture.

A *Cornish chough* is a name given to a black bird with red beak and legs.

Fishes are emblazoned in three principal positions: as *hauriant*, in a perpendicular position; *naïant*, or swimming horizontally; and as *embowed*, or bent. The *dolphin*, a very favourite device, is always borne *embowed*.

Man also appears on shields. He may be nude (a *wild man*, with shaggy beard, and a wreath of leaves round his loins; a *Moor* or *negro*; American Indians, &c.), or clothed, or in armour. Various parts of the human body are also shown. We have the open red hand (the badge of baronets of Ireland and of the United Kingdom), arms naked or *embraced* (clothed in armour). Arms are generally bent, *embowed* and *counter-embowed*. Legs appear bent, both naked and armoured. A singular type is afforded by the three naked legs of Sicily and the three armoured legs of the Isle of Man; these are bent at the knee and joined at the hip, so that they radiate like the spokes of a wheel. The heart often appears, in its purely conventional shape. Parts of the skeleton are common, such as and thigh bones.

The fabulous animals of heraldry are:—The *dragon*, a winged monster covered with scales, its tail and tongue being forked. The *griffin*, or *gryphon*, has the beak and claws of an eagle, the body of a lion, and is further furnished with dragons' wings and large pointed ears. These ears are of great importance in distinguishing the griffin, for it is said to have been one of the fiercest, most active, and quickest of animals. Gerard Leigh, a herald of the time of Queen Elizabeth, speaking of griffins, in a manner clearly showing he believed that they had a real existence, says, "I think they are of great hugeness, for I have a claw of one of their paws which should show them to be as big as two lions." Lady Mary W. Montague in one of her chatty letters, dated from Ratisbon (in 1716), mentions having been shown in a Roman Catholic Church a huge claw set in gold, which was said to be a griffin's claw. "I could not," says Lady Mary, "forbear asking the reverend priest that showed it, whether the griffin was a saint? The question almost put him besides his gravity, but he answered they only kept it as a curiosity." A *wyvern* is a dragon without hind legs, but with a serpent's tail, covered with scales and forked. The *cockatrice* is merely a wyvern with the head of a cock. The *pegasus* is a wild horse with wings. The *sea horse* is an animal possessing the fore quarters of the horse and a huge fish's tail. Many animals besides the horse are represented with fishes' tails, when they are said to be *marined*. The *mermaid* is a woman with a fish's tail. The mermaid is generally represented with a great abundance of coarse hair, and holding in one hand a mirror, and in the other a double-toothed comb. *Mermen* are also used in heraldry, the only difference being that the upper portion of the body is that of a man, and instead of holding the mirror and comb, they generally carry a barbed trident and a huge conch shell. The *unicorn* is a horse with a large pointed horn protruding from its forehead. The *harpy* is a bird with the head and breast of a woman. The heraldic *antelope* ought, perhaps, to be classed as a fabulous animal, for it is certain that no such animals as those seen on shields are known. It has the head of a stag, but with a tusk growing out from the tip of its nose, and it has rows of tufts down the back of its neck, on its chest, thighs, and on its tail.

*Centaur*s are sometimes used as a badge or as a charge.

(To be concluded.)

PRESENT-DAY WATER METERS.*

By WILLIAM SCHÖNHEYDER.

ALTHOUGH merely elementary knowledge, it is necessary to state at the outset that meters are divided into the following classes:—(1) Low-pressure meters; (2) inferential meters; (3) volume or capacity meters, without device for rendering them tight; (4) those of the Venturi class, which have a special function; (5) waste-detection meters, of the Deacon class; (6) positive meters, or meters which provide a space to be filled with and emptied of water, and which have some contrivance for rendering them tight at varying pressures and under diverse conditions of service. Before treating with each of these classes, it may be observed generally that they all have a useful purpose which they are capable of answering with more or less advantage according to their individual merits. The mistake most commonly made, in the author's opinion, is that they are indiscriminately used and frequently selected on account of first cost, without due consideration of the duty they have to perform.

The following table illustrates the large flows of water represented by leakages through comparatively small holes, when under a pressure of 100ft. head:—

Size of Hole.	Gallons.		Number of persons that can be supplied at 15 gal. cons. per head per day.
	Per Hour.	Per 24 Hours.	
$\frac{1}{16}$ in.	381	9,144	610
$\frac{3}{16}$ in.	214	5,136	342
$\frac{1}{8}$ in.	95	2,280	152
$\frac{1}{4}$ in.	24	576	38
$\frac{3}{8}$ in.	6	144	10

But a wider and more important question arises when the needs of our increasing population and the necessity of larger supplies come forward for consideration. Ten gallons per head per day of the London water supply admittedly represents waste. This quantity, based on a population of 5 millions, is 50 million gallons per day, or sufficient to supply 25 gallons per head per day to an increased population of 2 millions, or in other words, is more than sufficient for the needs of the city of Berlin. To put the matter (if possible), still more plainly, if this waste is permitted to continue £8,000,000 of capital, or one-fourth of the total approximate cost of the proposed Welsh scheme of water-supply (of 200,000,000 gallons per day) to London will be spent in order to make up the deficiency caused by preventable waste. Here is a great problem, and, as the author believes, the solution of it lies in the sale of water either by meter only (at very low prices it may be) or by meter with a fixed charge for a minimum supply at present rates in order to ensure health and cleanliness.

(1) *Low-Pressure Meters*.—These are more especially applicable to measuring small flows, such as dribbling supplies to flushing cisterns, but they can also be used for such services as supplies to private houses in which cisterns are used; the great objection to them is, as their name implies, that the whole of the pressure from the main is lost in passing through them, and therefore they require to be placed at the highest elevation at or from which a supply is to be taken, and this again involves—in the case of house supplies—the frequent entry of the meter-inspector and assistant to the top of the house for the purpose of reading the index and examining, repairing, or exchanging the meter. The oldest and probably the best known meter of this type is the "Parkinson," which much resembles a gas meter; it has only one moving part, namely, the drum, though it also requires at least one ball-valve for regulating the supply of water to it. It is very accurate

down to the smallest dribble and will work a long time without requiring repairs. The quantity delivered by the smaller sizes is, however, rather limited, for a $\frac{1}{16}$ in. meter is only rated to pass a maximum of 100 gallons per hour, a $\frac{1}{8}$ in. 200 gallons, and a $\frac{1}{4}$ in. 400 gallons per hour, or about one-third as much as meters of other kinds.

The "Bascule" is another meter of the low-pressure type, which also has only one moving part in the form of a double bucket, mounted on pivots, and so arranged that when one of the buckets is taking its supply from the main the other is being emptied, and *vice versa*; each bucket when full overbalances the other. In this meter also a ball-valve is required for limiting the supply.

(2) *Inferential Meters*.—As the name implies, the water is not actually measured in this type of meter, but the quantity passed through it is "inferred" from the number of revolutions made by the fan or turbine, which is the only moving part. These meters are exceedingly convenient and useful, as they are comparatively small, light and cheap, and they are fairly accurate when the water passes through at a good speed, as when used for filling water-carts, in filling large tanks (without ball-valves), or for similar purposes. When, however, the flow of water through them is frequently slow, their registration is very unsatisfactory, as the fan or turbine then

lags behind or stops entirely, while the water passes through freely. Probably the oldest and certainly the best known of this type was invented by the late Sir William Siemens in or about 1850. Two distinct kinds of this type are made, namely, the "Turbine" and the "Fan" meters. In the first the water enters through the top of a vertically placed wheel with turbine-shaped buckets, and being discharged from these in a diagonal direction the reaction of the water turns the wheel, which actuates the clockwork of the dial. Retarding vanes on the wheel prevent it from running too quickly at the higher speeds. The "Fan" meter has an upright spindle, but the wheel is driven by jets of water impinging on vanes secured to the spindle. In this country the turbine type is chiefly used, and abroad that of the fan type. The "Tylor Inferential" is another well-known meter. There is probably no very great difference in the value of the various types of inferential meters; vulcanite should count favourably in their construction, but they all fail to register small flows, yet in spite of this acknowledged defect they are habitually employed for measuring house services (and other dribbling supplies), with the result that the registered consumption, even in a water-closet town, is quoted at only five gallons per head per day and less; whereas, in reality, this should be nearer fifteen, or even twenty-five gallons per head per day.

(3) *Volume or Capacity Meters*.—These meters are almost exclusively made in the United States of America, and their use is chiefly confined to that country, though some are also used here. In construction they are, broadly speaking, all the same, as they consist of a casing of either gun-metal or vulcanite in which works a vulcanite block, serving both as piston and valve. They very seldom possess any provision for taking up wear, and the parts are, therefore, difficult and expensive to repair. Hence (though they profess to measure the volume passing through them), as they are not tight even when new, they cannot measure small flows, and their leaky condition is necessarily augmented by wear.

* A paper read before the Institution of Mechanical Engineers on January 26th, 1900.

A VALUABLE BOOK OF REFERENCE for nothing may be obtained by every reader of the BUILDERS' JOURNAL who will display a little energy in a good cause. For particulars see page 35.

Their merits appear to be simplicity, small size, lightness and cheapness, and for large flows they are said to be very accurate. The "Hersey," the "Crown," the "Bee" or "Thomson," the Kent "Uniform," the "Nash," and some others belong to this class.

(4) *The Venturi*.—The possibility of constructing the Ven'uri meter is due to the practical absence of loss of head in the main, which is contracted and again expanded by means of properly formed cones. The difference between the pressure where the water is passing through the main pipe before arriving at the meter, and where it is passing through the neck of the tube, forms the index for gauging the flow. These facts were discovered over 100 years ago by the Italian philosopher Venturi, and the meter has been perfected by Mr. Clemens Hershel, of America. It has no moving parts, except the registering gear, driven by clockwork; it is cheap considering the large volume of water it deals with, and for ordinary rates of flow in water-mains it is said to be very accurate; it is certainly most convenient and useful, but it must, of course, not be used below its rated capacity.

(5) *Waste-detection Meters*.—A very simple and effective meter of this class has been invented by Mr. G. F. Deacon, of Liverpool, and it is in very extended use. The water enters the upper (and smaller) end of a conoidal tube (though in some of the meters it passes upwards from below) in which is mounted on a rod a circular disc, so as to be able to move freely up and down. As the flow increases the disc will fall, and will rise when it decreases; its motion is communicated to a pencil outside the meter by a thin metallic cord passing through a gland, and suitably counterweighted. The movements of the pencil are traced on a sheet of moving paper with divisions representing hours (generally twenty-four). A diagram is thus traced which indicates to the initiated the varying flow through the main, and the exact rate in gallons per hour can be measured for any time of the day or night, and by these means waste is readily detected.

(6) *Positive Meters*.—The aim of all positive meters is to accurately (positively) measure and record the water passing through them, hence they have each one or more cylinders (with their pistons and valves), which are alternately filled and emptied; and, of course, they have suitable counters. The "Kennedy" meter still retains its high reputation. Nearly all the other types of positive meters have two measuring cylinders with their pistons and valves, and are of the "Duplex" class, in which the piston of one actuates the valve of the other. Some have their cylinders horizontal, and others have them vertical. The best known are: The "Frost," the "Tylor Positive," the "Worthington," the "Fraser," the "Schreiber," the Kent "Absolute," the "Goodwin," and the "Schmid." Next in importance to accuracy, durability, simplicity and general efficiency must be considered the quantity of water delivered under a given effective head. Judged from this standpoint the "Kennedy" is far ahead

of all others; the "Parkinson Low-Pressure," the Siemens "Inferential," and the "Tylor Positive" are much below the average in this respect.

Early in 1884 the author's attention was directed by one of the largest London Water Companies to the great want of a good water meter, which should be free from the defects of those already in use, and which should, above all, be simple, and should be able to register the smallest dribbles for long periods without liability to derangement. After considerable study and many experiments he has produced the type called the "Imperial," shown in the accompanying illustrations.

The meter consists, as will be seen, of the following parts:—The lower portion or body A, containing the three cylinders B, and the valve-seating C, with its three ports and passages D, communicating with the bottom of the cylinders; and there is a discharge port and passage E. Inlet and outlet connections F and G and strainer H (Fig. 5) are also attached to the body portion. I is the cover with the rib K for holding down the strainer, and it has a prolongation at the top for receiving the counter gear. The unequal division of the bolt-holes prevents the cover from being wrongly fixed to the body. Though the counter gear contains a few novelties, such as the entire absence of brackets, screws, springs and small pins, and has a conveniently hinged glass cover, still essentially it does not differ very much from the counters of other meters. L (Fig. 3) is the valve with its three arms, in the ends of which are cup-shaped bushes for receiving the spherically-shaped heads of the piston-rods M (Fig. 1); and to these are secured the pistons, composed of upper and lower piston-plates, nuts, and flexible piston packings. The water enters the meter, as shown by the arrows, passes up through the strainer into the upper portion of the casing and presses equally downwards on all the three pistons, and also on the valve. According to the position of this valve, the lower end of each cylinder in succession is communicating with the outlet passage, and its piston is therefore forced down by the superior pressure above, and thus discharges the contents of the cylinder. At the same time one or both of the other cylinders is having its piston raised, by which water is drawn in through the passages and the lower part is filled. Thus each lower end of the three cylinders B is in due course filled and emptied, one or two pistons always supplying the active force, so that there is no dead-point. The length of the stroke is regulated by the flanged projection

N, Fig. 1, on the valve L coming into rolling contact with a similar flange O on the valve-seating C; a slight skew of the ports causing the pistons to endeavour to take a longer stroke than they should, and the roller-paths restricting this tendency. The teeth in the valve and the notches in the valve-seating prevent the valve from turning round on its own axis (see Figs. 3 and 4). A pin in the upper part of the valve engages the crank of the crank-spindle P, Fig. 1, which communicates motion to the clockwork in the usual manner. The pins through the upper ends of the piston-rods prevent the pistons from falling out of the cylinders should the meter be turned upside down.

It will be seen from the above description that the meter is positive in its action, that the lengths of stroke are definite, that the speed of water through it is practically uniform (as in a three-throw pump), so that there is no concussion or water-hammer, that there is no backlash between any of the working parts, and that the meter can therefore be run at any convenient speed without noise. It has few working parts, not a stuffing-box nor a spring among its details, and is self-lubricating. It contains no small parts, neither pins nor screws; the three studs and nuts (permanently securing the valve-seating), the cover-bolts, and piston nuts are the only appliances of the sort used. As soon as the cover has been removed, the whole of the working parts can be taken out, examined, cleaned, new piston-cups fitted, and other ordinary repairs effected, if necessary, even without removal from its position in the pipe line. The only joint which has to be made is that between the body and the cover, and any leakage here is at once detected, as it is outwards.

AN INTERESTING CORNISH CHURCH.

THE Collegiate Church of St. Crantock (Newquay, Cornwall) consists of a nave with south porch, chancel, north and south transepts, and chancel aisles. There is also a western tower, no part of which is at present visible from within the fabric. No traditions exist as to there having been a church in Saxon times, the earliest evidences of building being seen in the north transepts, where the corner blocks, with their double buttresses, are of Norman workmanship. In the thirteenth century the lower part of the west tower was erected. The chancel seems to have been slightly lengthened. The south chancel aisle, if not added in the thirteenth century, underwent considerable repair. The east window relieving arch is of fourteenth century character, but this has been rudely cut away to make room for a seventeenth century arch, which is now filled with a window. The fine chancel arch was built in the thirteenth century. In the following century the chancel arcades were reconstructed. There are no remains of any tracery of this date, although some may be discovered hidden under the moulds on the north side of the church. Early in the fifteenth century the west tower fell above the nave roof, destroying the font; and the tower was then rebuilt, but so badly that several cracks give a dangerous appearance to this landmark. One of the most interesting features in the church is the existence of fragments of the old fourteenth century parclose screens. These are quite unique in Cornwall, and there is enough in existence to make them of great interest after careful repair. Portions of the original chancel screen of an unusual type exist at the entrance to the rood loft, having been formed by burrowing through the north respond, which is of great thickness, owing to the existence of the twelfth century tower. The nave roof is entirely hidden from view by plaster; this will be taken off, and the old timbers, after conservative treatment, exposed to view. Beautifully carved fragments of fifteenth century bench ends have been discovered under the floor of the pews. The chancel roof was plastered up eighty years ago—even the moulded principals and purlins

were treated in the same way. The chancel aisle roofs are of deal, having been erected about a century ago, and on removing the plaster a generation of owls' nests was found. Serious leakages have been neglected for many years, as may be seen by the gentle cascades that trickle down the transept responds and north transept walls, so that they are quite green and are never dry. The very uncomfortable pews contain seats only 10in. wide, and are quite unsuitable. The upper part of the tower is in a miserable condition, and it is only owing to the mere weight of masonry that it has not collapsed. The work of careful restoration of the church is to be taken in hand at once. Mr. Edmund Sedding estimates it to cost about £3,000.

CONCRETE FLOORS.*

By FRANK CAWS, F.R.I.B.A.

TIME was when all London houses were built of wood. Then came the Great Fire, after which brick walls were insisted upon. This was one important step in the right direction, but up to the present, in the case of dwellings, this step has not been very much advanced upon. It is true that in buildings of a costly character, such as banks, picture galleries, theatres, museums, and so on, very considerable advance has been made in the direction of fireproof construction, but not in respect of buildings in which the risk of fire concerns human life, rather than valuable property. It would seem from this that Englishmen place a higher value upon property than upon life. I do not myself believe for one moment that such is the case, for we are not living to-day under the laws which permitted the hanging of a man for stealing a sheep. The question of fireproof dwellings is one of ways and means. It must be obvious that, if by making buildings fireproof we make them so much more expensive that people in general cannot afford them, it is better to have a non-fireproof dwelling than no dwelling at all. But I am convinced that it is quite easy to construct fireproof dwellings at such a slight additional cost to non-fireproof dwellings that there is no proper excuse now remaining for those who continue to favour the latter. The question of the best method of fireproof construction is a very debatable one, and relates more particularly to floors and roofs.

I have been engaged on many concrete floors, in all of which I have adopted the slab principle successfully, varying the mode of construction in sundry details with the special requirements of each case, and as further experience suggested. I have always been particular to obtain rigid strong centering, and I cannot too emphatically caution my fellow architects as to the importance of this item. Any attempt to save money by scamping the centering is likely to lead to trouble, and to prove very false economy. The greatest difficulty in dealing with cement-concrete floors is due to the natural expansion which the material undergoes in process of setting. This expansion is much greater when the cement is new and hot than when it is old and cool. It is not, however, the expansion itself which causes the trouble so much as the smaller degree of contraction which follows expansion in the process of setting. This contraction causes cracks, which generally occur over the supporting girders, where the concrete is generally thinnest. These cracks have really no appreciable effect upon the strength of the concrete, but all the same they are apt to cause uneasiness and want of confidence in the minds of those who do not understand what causes them. By using carefully selected cool cement, and by taking certain precautions as regards the size of the slab and its mode of casting, the shrinkage can be so minimised as to almost entirely avoid such cracks. I would like to point out at this stage that I consider sand a most improper material to mix with cement in concrete floors. In fact,

I regard it as poison to the cement, and have never allowed its use since the discovery I made at the early stage of my experience as to its bad effects. The fact is, if a very fine sand be used, instead of helping the cohesion of the concrete it tends to disintegrate it, so that when sand is employed to give the necessary smoothness to the finishing of the upper surface of the cement-concrete floor the surface when subjected to the traffic is likely to scrape off and to give off sandy dust, and eventually present a very shabby appearance; therefore, in finishing the surface I have found it best to employ fine crushed granite instead of sand.

In making fireproof floors for cottages I consider, if proper care were taken in the centering, it would be better to do without plaster ceilings altogether, and be content with the natural impression of the wood upon the cement, whitewashed. By such means, and also by avoiding needlessly thick slabs, the expense of such floors can be brought within such limits as to render the fireproof dwellings of a working man cheap enough to be a good commercial investment. During all the years I have been interested in fireproof construction I have been increasingly impressed with the fact that the greatest field open for the ingenuity and skill of the architect and builder is to be found in the direction of providing fireproof dwellings for the people at small cost, in lieu of those match-boxes which are now multiplied by the thousand in our large cities in apparent defiance of all desire of improvement. Although a fireproof dwelling must cost more than a non-fireproof one, it will pay best in the end, because it does not decay or fall into disrepair, but, where ordinary care is used, is practically everlasting. Moreover it is vermin proof, and cleaner and more sanitary than buildings containing many hidden chambers and cells of decaying timber.

The limitations as to the size of cement-concrete floor slabs are largely determined by the quantity which a gang of men can cast in one day. In designing a large expanse of flooring it is necessary to sub-divide the area into squares of reasonable extent, and I may say that in my own practice I consider a square about 150 superficial feet, a reasonable size to arrange for, although in some cases I have found it necessary to make them much larger. The steel girders, which form the divisions between the slabs, should be made strong enough to carry the weight of the slabs themselves and of their greatest proposed loads; but it must not be supposed that when the slabs are set hard these steel girders will necessarily be called upon to sustain these weights. I say necessarily, for much depends upon the manner in which the girders are placed. We, as architects, should be extremely careful about our work, to allow a large excess of strength; but we should be likewise able to distinguish between a mere excess of strength and an excess of cost at the expense rather than the gain of strength. Some people think that cement floors are too cold, and accordingly cover them with wood, which, of course, is a very great addition to the cost, having nothing but the sense of comfort to recommend it. For my own part I think that a cement floor covered with a good cork carpet is very much preferable and quite comfortable. However well seasoned wood flooring may be, the boards will shrink and, when the floor is washed, the moisture between the chinks cannot get away or be evaporated without in time tending to produce an undesirable state of mildew or decay. Seeing that the stress of slabs under uniformly distributed loads is proportional to the cube of their span, it will be obvious that great reduction of stress is obtainable by forming the slabs with coved edges. Suppose, for example, we are dealing with slabs about 12ft. square, similar to those I have recently had cast at Messrs. Swan and Hunter's new offices at Wallsend, and we reduce the flat part to 10ft. square by means of our cove, the greatest stress is reduced accordingly as from the cube of 12 to the cube of 10, that is, about 24 per cent., and at the same time these coves serve to enclose the steel supporting girders, thus protecting them

from fire. If time permitted there is much more I might have said on the subject, not only on concrete floors, but also on concrete roofs, which, from a fireproof point of view, are certainly not less important.

Thus far my remarks have been so discursive that I feel it necessary in closing this lecture to focus, in the form of general rules, some of the conclusions to which twenty years of special experience have led me in regard to the construction of concrete slab floors:—

- (1) Take pains to obtain old cement.
- (2) Use good broken brick aggregate, and not sand, in the proportion of four of brick to one cement, for the body of the slab, and finely crushed granite without sand for the surface coating, having about three of granite to one of cement.
- (3) Adopt, as precautionary provision, sheep wire netting as the base, and steel angle or tee bars weighing more than 1½lbs. per lineal foot, spaced about 3ft. apart on the netting.
- (4) Consider a slab 10ft. square by 4in. thick as capable of sustaining a load of 9cwt. per foot, including its own weight, and reckon that every slab will bear, per square foot, more or less than 9cwts. directly in proportion to the square of their thickness, and inversely in proportion to the cube of their span. When the slab is rectangular the minimum span has to be considered the span.
- (5) Avoid casting slabs in frosty weather.
- (6) Insist upon organising the gangs of workmen so as to cast as large an area of slabs as possible in one heat, and never allow a slab to be left overnight with its area only partially cast.
- (7) Insist upon strong centering, and keep it all standing not less than five weeks after the last slab of the series of one flat is cast, and to absolutely forbid the sudden and careless removal of the centering. In conclusion, you must understand that in making no reference to many other methods of concrete flooring, which are more or less successfully practised, I have no desire to cast any reflections upon them, but have thought it best to confine my remarks to my own experience, and to speak the things which I know rather than those of which I have heard. Thirty years ago Messrs. Pedder and Brannon, architects, erected near the gas works at Hendon, Sunderland, two concrete cottages, which, after completion, they filled with straw and other combustibles and, in the presence of a company of well-known Sunderland townfolk, set fire to. No visible damage resulted at that time, and the cottages have been occupied by tenants, I believe, ever since. A few weeks ago the present proprietor took me down to inspect them. I found them in excellent condition—in fact, as good as ever they were. The working people occupying them are paying good rents, and the proprietor is about to build four similar fireproof cottages adjoining, plans for which have been recently approved by the Sunderland Corporation. The test of a fierce fire, and of thirty years subsequent wear and use, permit no other conclusion than that fireproof cottages for the people can be built cheaply, substantially and sanitarily. And in this case the proprietor finds little or no structural repairs needed after thirty years rough use. I think we shall do well to lay these facts to heart, and each do what we can to provide fireproof houses for the common people.

Mr. George Furness, of Willesden, contractor for the Thames Embankment from Westminster Bridge to Somerset House, and other large schemes, who died on January 9th, aged 79, left property of the value of £303,826 11s. 7d., with net personalty of £180,680 7s. 7d.

Barnsley's new Smallpox Hospital, which has been built at Lund Lane, Monk Bretton, at a cost of £7,500, comprises an administrative block for ten nurses and eight servants, all the necessary offices, disinfecting apparatus, &c., for a large hospital, and the hospital proper, with accommodation for fourteen beds. The hospital, which will serve a population of 100,000, is so planned that the accommodation can be quadrupled, if needful, without any additions to the administrative or other blocks.

R.I.B.A.

THE PALACES OF THE PARIS EXHIBITION, 1900.

By CHARLES LUCAS.

A MEETING of the Royal Institute of British Architects was held last Monday evening, Mr. William Emerson in the chair. The minutes of the previous meeting having been confirmed, the president introduced Monsieur Charles Lucas, who, he said, had been one of their most energetic honorary corresponding members since 1881. M. Lucas then read, in French, his paper, entitled, "Notes on the Palaces of the Paris Exhibition, 1900," which was illustrated with 137 photographs and drawings, which are on view at No. 9, Conduit Street, for a few days. The following is a summary of the paper:—

The Exhibition occupies an area of about 112 hectares (1,120,000 square metres) apportioned thus: Champ de Mars, 50; Trocadéro, 16; Esplanade des Invalides, 12; Champs Elysées, 15; Quays on the left bank of the Seine, 9.50; Quays on the right bank, 9.50. In addition, in the Bois de Vincennes, 110 hectares (1,100,000 square metres) have been provisionally taken for special exhibitions, various sports, houses for the working classes, &c. The superficial area covered in will not be less than 450,000 sq. metres—the French section occupying 250,000, the foreign section 170,000 and the Bois de Vincennes 32,000. The private buildings of the foreign sections along the left bank of the Seine cover a superficial area of about 50,000 sq. metres. Besides the buildings above indicated there are 100 French pavilions, numerous restaurants, kiosques, cafés and drinking bars, as well as seventy-five pavilions or foreign edifices, beyond the official pavilions of the nations represented at the exhibition, numbering thirty-six.

It is calculated that the total weight of iron and steel employed in the French official palaces alone amounts to 50,000 tons; and for the motive power and the electric lighting there has been provided a total force of 20,000 horse-power, which in case of need can be brought up to 40,000. The power of the cranes used is 425 tons. Some 5,000 workmen are daily employed on the works.

The selection of architects for the principal palaces was determined by public competitions. The twenty-three workyards, under the general supervision of the architectural department, have at their head twenty-three architects, all premiated in the two competitions for the erection of the two permanent palaces in the Champs Elysées. These architects, among them seven former students of the Academy of France at Rome, are surrounded by colleagues chosen by themselves among old fellow-workers in offices, the École des Beaux-Arts or the *loges*, that is to say, among old pupils of the same masters, who have shared in the same artistic struggles. Thus the buildings are a resultant, if not of the tendencies of the French School of Architecture, at least of the methods of study of its students. Of all the buildings two only will remain permanently, the two palaces in the Champs Elysées, which are intended for Fine Art Exhibitions. The others will be demolished immediately after the close of the exhibition in November.

M. Lucas then went on to describe the following buildings more or less in detail:—

1. *The Monumental Gateway on the Place de la Concorde* (M. Binet, architect).

2. *The Small Palace on the Champs Elysées* (M. C. Girault, architect).—This building, slightly modified since first designed, retains all the charm which captivated the jury and the public at the time of the competition, and won for its author the appointment of chief architect of the two palaces of the Champs Elysées. In course of its erection M. Girault and the architects of the Great Palace agreed upon certain modifications for the sake of

harmony between the Great and Small Palaces, which are intended to make a monumental whole, ornamenting the new Avenue des Palais, and forming together, with the Pont Alexandre III., the architectural legacy of the exhibition of 1900.

3. *The Great Palace*—in three sections: (1) The anterior section on the Avenue des Palais, M. Deglane, architect; (2) the central section, M. Louvet, architect; (3) the posterior section, M. Albert Thomas, architect. This is the most important of the permanent structures. Each section, especially the front and rear, combines in itself a complete edifice. The three architects, each making a sacrifice of some of his artistic idea, have contrived a completely harmonious whole, in which stand out portions of great beauty and personal feeling. The central section has two fronts, of which the northern, fronting the Avenue des Champs Elysées, is raised upon a podium. One of the most remarkable motives, not only of the Great Palace, but of the whole of the Exhibition buildings, is the grand staircase—a real staircase of honour for the most stately ceremonials—leading from the ground floor to the Concert Hall and galleries on the first storey. The conscientious study in metal, and particularly of the iron gutter, is strikingly noteworthy from the point of view both of construction and decoration, combining as it does boldness and elegance. The rear section of the Great Palace forms a complete and fascinating whole, with its great central hall, crowned by an elliptic dome, with its straight staircase, its galleries, and its saloons. Behind the Ionic order which decorates the main front runs a high enamelled frieze, the work of the national manufactory of Sèvres, the varied tones of which will be lit up by the setting sun.

The Pont Alexandre III. (MM. Cassien-Bernard and G. Cousin, architects).—In the course of his remarks on this bridge, M. Lucas said that it would always remain an irrefutable witness of the necessity of the alliance between architects and engineers in works of public utility. Referring to the rich Ionic order and the sculpture which decorated the two palaces and the bridge, the only artistic monuments which would survive the exhibition, the author said that they recalled the luxury displayed by Louis XIV. in his royal residences, and occurring as they did under a Republican Government in such an eminently popular manifestation as a universal Exhibition they were significant to show that Art was an essential need of France whatever the institutions in force at the time.

Coming to the temporary buildings, the author went over the various plans and original working drawings illustrating each building, and gave a brief commentary upon each. These temporary structures are as follows:—

The Pavilion of the Town of Paris (M. U. Gragny, architect).

The Palace of Horticulture (M. C. A. Gautier, architect).

The Palace of Social Economics and Congresses (M. Mewès, architect).—In this palace rooms are specially arranged for the International Congresses, two of which, the Congress of Architects (July 29th to August 4th), and the Congress of Public Art (August 6th to August 11th), the author said seemed to invite the presence of English architects.

The Théâtre des Bonshommes Guillaume and the Aquarium (MM. Henri and Albert Guillaume, architects).

Old Paris (restoration by M. Robida).—This is a complete mediæval town, covering a spacious area, built on piles, and containing gates and commune house, turrets, *bretèches*, and famous houses, old markets and theatre, grand hall of the palace and chapels, well, and pillory, stalls, shops, taverns, &c.

Pavilion of the Egyptian Section (MM. P. F. Boulad and M. Dourgnon).—This is composed of three blocks—(1) A Temple of Ancient Egypt; (2) an Arabian Bazaar; (3) a Theatre with façade of Ancient Egyptian style.

Palace of the Algerian Section (M. Albert Ballu, architect).—This reproduces the minaret of the Mosque of the Sultan Bashaw at Oran,

the cupola of the Mosque of La Pêcherie at Algiers, the Moorish court of the Old Museum of Algiers, &c.

Palaces of Navigation, Commerce, Woods and Forests (MM. Tronchet and Rey, architects).

Palace of Education, Teaching, Instruments; and General Processes of Letters, Science, and Arts (M. Sordais, architect).

Palace of Civil Engineering and Means of Transport (M. Jacques Hermant, architect).

The Château d'Eau and Palace of Materials and General Processes of Mechanical and Chemical Industries, &c. (M. Paulin, architect).

—This, crowned by the crest of the Palace of Electricity, promises to be, in combination with the latter, one of the great attractions of the Exhibition. In the evening strings of electric lights will illuminate the main architectural lines and the cartouche, and the various water effects, cascades, and jets, will be rendered luminous and coloured with every hue.

Palace of Electricity (M. Eug. Hénard, architect).—In this palace, surrounded on all sides and partly masked by the Château d'Eau, the architect has concentrated his whole decorative effort in the upper part of the central hall, which is in the form of a trilobate vault containing the great niche of the Château d'Eau. The building is surmounted with a broad open-work crest, which during the day will give the impression of metal lacework standing out against the sky, and during the night the appearance of lacework of flame.

Other palaces described were the *Salle des Fêtes* (M. Raulin, architect), adapted from the Machinery Gallery of the Exhibition of 1889, and to remain permanently as a hall for the award of prizes; *Palace of Woven Fabrics* (M. V. Blavette, architect); *Palace of Mines and Metallurgy* (M. Varcollier, architect); *Palace of Belgium* (MM. Acker and Maukels); *Palaces of National Manufactures* (MM. Toudoire and Pradelle); *Palace of Decoration and Furniture* (M. Esquié, architect); *Palace of Various Industries* (MM. Larche and Nachon, architects); *Palace of Ceramics, Crystals and Glasswork* (M. Tropey-Bailly, architect).

In his closing observations M. Lucas said that throughout all the conscientious work, in the heart of which is paramount the influence of the school in which the architects and their collaborators had been trained, there is observable, especially in the richness of the decoration and the exuberance of the sculpture, a certain exoticism, a reflection as it were of architectural styles that have come ready-moulded from the furthest East, giving rise to thoughts of Colonial France and its art.

Touching the remuneration received by the architects of the Exhibition, M. Lucas quoted from a report of the Minister of Commerce to the President of the Republic: The remuneration was fixed and comparatively small. The chiefs of offices, men of tried skill and assured reputations would easily find higher remuneration in private work. The more meritorious is the zeal with which they devoted themselves to the service of the State.

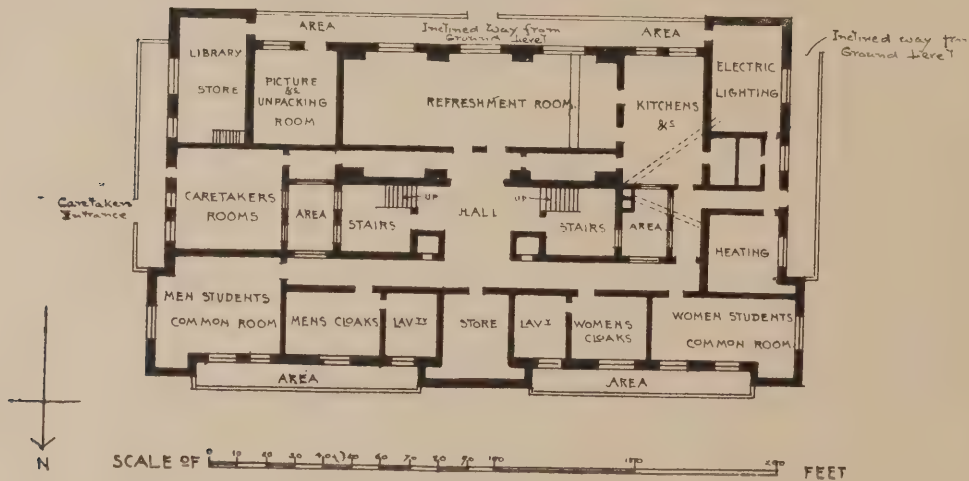

A vote of thanks to M. Lucas was then proposed by Mr. F. C. Penrose and seconded by Mr. H. H. Statham. Mr. Locke, secretary to the Institute, announced that the drawings and photographs had been given to the Institute by the authors of the designs for their permanent property. Mr. Emerson put the vote of thanks, which was heartily agreed to, and on his motion a vote was also passed to Monsieur J. Bourard, the director of the architectural works of the Exhibition, and to those architects who had joined in presenting the collection of drawings to the Institute. He then announced that a special meeting would be held on March 5th to propose a suitable recipient for the Royal Gold Medal, after which a business meeting would be held to consider a series of recommendations of the Council with respect to the composition and election of the Council under by-laws 25, 29, and 30. The Congress of British Architects would be held in their rooms from March 18th to March 23rd on similar lines to those of other professions. The meeting then terminated.

THE BACTERIAL TREATMENT OF SEWAGE.*

By HERBERT T. SCOBLE, A.S.I.

BRIEFLY speaking, bacterial treatment is a return to nature's method of sewage purification. The necessary microbes are always present, and the aim of the various systems is to afford the best possible conditions, consistent with reasonable expenditure, for the multiplication and action of these beneficent organisms. Bacterial action is altogether stopped if the sewage is strongly acid. Bacteria can be roughly classified as (1) parasitic (needing a living host), (2) saprophytic (living on dead animal or vegetable matter), and (3) those which adapt themselves to circumstances and exist indifferently as parasites or saprophytes. They vary in size from $\frac{1}{10000}$ th to $\frac{1}{250000}$ th of an inch in diameter. Multiplication usually takes place by division. As Cohn puts it: "Let us assume that a microbe divides into two within an hour, four in the second hour, then again into eight in the third hour, and so on. The number of microbes thus produced in twenty-four hours would exceed $16\frac{1}{2}$ millions; in two days they would increase to 47 trillions; and in a week the number expressing them would be made up of 51 figures." Professor Boyce has found 750 million organisms in a cubic centimetre of fresh sewage.

Bacteria are also distinguished according to the conditions under which they live, and may be either anaërobic (living without air, that is, without free oxygen) or aërobic (existing with free oxygen). All bacteria are destroyed if allowed to remain too long in contact with their own products. In the absence of water, or, at least, moisture, they are unable to multiply, and become dormant. The work they do in the purification of sewage is first to break down and then to oxidise the foul matters of which it is partly composed.

Unfortunately the word "filter" has been applied to bacteria beds, and its use is so extended that it will have to pass. No mechanical action takes place, and the sewage is, therefore, not "filtered" in the true sense of the word. The material in the beds is there to afford a resting place for the bacteria, which, in its absence, be carried away with the effluent.

The systems in use can be divided into two classes, the first of which has as its object the destruction of the impurities by aërobic organisms, while the second consists of a primary decomposition by anaërobic and a secondary purification by aërobic action. The ideal system would probably provide for three separate stages of treatment—(1) an aërobic, (2) anaërobic-aërobic, and (3) aërobic. Pathogenic organisms or disease germs are, as far as our present knowledge goes, either destroyed or enfeebled in passing through an installation. Where the effluent is discharged into tidal waters an anaërobic process only is required.

Bacterial systems have this strong recommendation, that they produce no sludge. The annual cost of up-keep is, with automatic gear, nominal amount; where it is not provided, constant attendance is necessitated. The beds require raking over from time to time owing to the production of a surface film and the growth of weeds, which in warm weather is very rapid. Where screens are employed, the matter retained must be speedily taken away. I doubt whether it is worth while to include an item under a heading of "annual expenditure for the removal of the burnt-out ash." The septic tank at Belle Isle, Exeter, has taken the sewage, without screening, from 1,500 people or over three years and a half; no mineral residue has yet been removed, and the quantity of such matter in the tank in no way interferes with its efficiency. Under

The Dibdin or Sutton System

The sewage first passes through a screen which retains solid faeces, string, rags, paper, &c. It then flows on to a coarse bed of coke

breeze, ballast, or other similar material, the individual pieces of which vary in size from $\frac{1}{2}$ in. upwards. The sewage is distributed by one or more channels over the top of the bed, which is filled to within 3in. or so of its surface. It is collected on the floor of the bed by rows of agricultural drain pipes joining one main collector. After a contact of some definitely arranged duration, the discharge valve is raised and the effluent is received by a second filter. This is made up of the same material as in the first bed, but the particles are much finer; dust, however, is rigidly excluded. Series of coarse and of fine beds are provided so that each may have a rest after discharging. Assuming an 8 hours' cycle and 2 hours' contact to have been settled on, the first bed will be filled (1 to $1\frac{1}{2}$ hours), stand full (2 hours), empty ($\frac{1}{2}$ to 1 hour), stand empty ($3\frac{1}{2}$ to $4\frac{1}{2}$ hours), and then be filled, &c., again. The sewage will run into the second filter while the first is standing full, and so on. The materials employed in the construction of installations on this system are of widely different character. Beds may be made by digging pits in clay and burning the same for ballast, which is then screened and returned, but such works cannot be considered of a permanent nature. Again, I have seen beds the walls of which were of clay, the floors of concrete rendered in cement, and the filtering material coke. In this case the sewage was distributed by rows of perforated cast-iron (rain water) pipes laid on the surface of the coke, and it was collected in the usual manner. To make certain that the works will last, the floors should be of concrete and the walls of either concrete, brick or stone; all internal surfaces should be rendered in cement, and coke or furnace clinker should be used in preference to ballast. Beds have been made of many different depths with satisfactory results. The amount of fall available usually fixes the depth that can be given to the beds, but where an unlimited fall is obtainable the time occupied in filling and discharging regulates this dimension. The filling of a 13ft. bed would occupy a considerable time when the flow was slight, and the sewage would therefore be kept in the bed too long. On the other hand, if the beds were very shallow, the cost of construction would be much increased.

Colonel Ducat's Method.

of purifying sewage is to expose it to air as much as possible. Instead of building solid walls round the filtering material (vitrified clinker $\frac{1}{2}$ in. to $\frac{1}{2}$ in. in size) it is encased in agricultural drain pipes set in cement, the whole on a concrete floor. These pipes are tilted inwards at such an angle that the liquid cannot escape. At intervals layers of 3in. pebbles extend right through the bed. During winter, owing to constant evaporation, the beds would freeze were they not enclosed and warmed by a supply of hot air.

The Scott-Moncrieff System

provides separately for each of the three stages of purification. Anaërobic action takes place in a chamber containing successive strata of flint, coke, and gravel. The sewage passes up through a false bottom, rises between the flints, &c., and flows at its original level or thereabouts on to a thin layer of filtering material on a tray. It passes continuously through this, then falls a few inches and encounters other similar layers. The anaërobic action in the first chamber produces amongst other substances ammonia. This is converted by the bacteria in the upper filters to nitrous acid (nitrites). In the lower layers the aërobic present change the nitrous acid into nitric acid (nitrates). The results are very good, but the cost of constructing the trays must be taken into account when comparing this with other systems.

The Septic Tank System

is so called because the purification of sewage is begun by a process of putrefaction. The products of this first stage are passed on to fine filters where oxidation takes place. The installations on this system are uniform in character but differ widely in extent. The

tanks generally have arched roofs covered with soil and turf, but joists and concrete are sometimes used—manholes are built in to allow inspection. The filtering material is broken furnace clinker (preferable) or coke from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. in size. In a typical installation a grit chamber retains the road detritus. The sewage is conveyed by special inlet pipes to some 18in. or so below the water level of the tank. A main distributor conducts the tank effluent to the automatic gear, and rows of half-channel stoneware pipes distribute it over the filters. Under this system no screening is done. All the solids, other than road grit, enter the tank, and are there liquefied or turned into gases by anaërobic action. There is, therefore, no smell from untreated sewage. The final effluent is bright and without smell. The inodorous gases given off produce a great deal of heat when burnt, and the tank holds from eighteen to twenty-four hours' flow of sewage, and any particular discharge of foul matter soon spreads. The fall desirable for the septic tank system is 4ft. to 5ft., but less will suffice in case of need.

According to Dr. Garfield, coal makes a most excellent filtering material. The beds are arranged so that the larger particles are at the bottom, those of medium size next, and the fine ones on the surface. The chief feature of

The Polarite Biological Sprinkler System

is the method of distributing the sewage over the beds. The description of the Candy-Caink gear will show how this is done. The sewage is first treated in a small detritus chamber designed to hold the flow of half an hour. A screen at the further end prevents the solids from passing on, and it is claimed that they are broken up by bacterial action. Where sufficient fall is not available to allow two filtrations, a "sludge digesting bed" is employed. This is very similar to the first chamber in the Scott-Moncrieff system. The filters are made up of layers of "polarite" and gravel.

According to Dr. Clowes, the points of advantage of bacterial over chemical treatment are:—(1) It requires no chemicals; (2) it produces no offensive sludge, but only a deposit of sand or vegetable tissue, which is free from odour; (3) it removes the whole of the suspended matter, instead of only about 80 per cent. of it; (4) it effects the removal of 51.3 per cent. of the dissolved oxidizable and putrescible matter, as compared with only 17 per cent. removed by chemical treatment; (5) the resultant liquid or effluent is entirely free from objectionable smell, and does not become foul when it is kept; it further maintains the life of fish. (Details of the reports of the experts appointed by the Manchester Corporation, in favour of bacterial treatment, are given in the supplements to the issues of the BUILDERS' JOURNAL for November 22nd and January 31st last.)

Automatic Gear.

With automatic working it will be possible to deal with the sewage of a district by separate installations at different sites, without adding in any great degree to the cost. Extensive sewerage and pumping will thus often be avoided. The advantage of employing automatic alternating gear was first recognised in connection with the septic tank system. The original automatic alternating gear of this system is still at work, but the forms now generally adopted occupy less space, and are designed to meet varying requirements. Thus, one form provides for a timed discharge; in another an overflow from the second bed fills a bucket, which then drops and raises the discharge valve of the first bed, and so on; a further type of gear, designed for small installations, say for an asylum or country house, has for its object the control of the flow on to the filters. Were the flow not regulated the beds would receive the merest trickle at night, and in the morning an altogether excessive amount. As this might impair their efficiency the flow is stored in the tank until just enough has accumulated to fill a bed. With this gear three beds are generally provided; any two work alternately while the third is resting.

* Résumé of a paper read before the Surveyors' Institution on February 12th, 1900.

Adams' syphonic apparatus consists of an air-controlled supply and a timed syphonic discharge. Ridgway's automatic distributor is operated by the rise and fall of a float to which a pawl is attached. The Caidy-Caink distributor consists of two arms, each perforated on one side and connected with a central bucket, which in turn communicates with and is fed from a trough. The distributor revolves as the sewage emerges from the perforations, and the liquid is thus sprinkled evenly over the bed. The normal flow of four minutes is dealt with at once and causes the sprinkler to revolve for one minute.

The first point in connection perhaps with any and every scheme is—what will it cost? In every case the aim of the surveyor will be to avoid pumping, if by any means he can do so. This may at times be accomplished by reducing the gradient of the sewer for some distance from the outfall. The levels of the proposed site or sites should be accurately taken and the invert of the sewer marked on the plan. The fall that can be allowed will then be ascertained, but it must be borne in mind that the effluent will have to pass over land whenever a Local Government Board loan is wanted. Existing outfall works should be inspected, as it may be possible to adapt them. When the sewage is purely domestic no difficulty will be experienced in effectually purifying it by bacterial treatment. If fibre from wood pavements has to be dealt with, it will require special provision, as it is essential for its speedy dissolution that it be subjected to a definite anaerobic process. Trade discharges must be carefully considered, and the normal dry-weather flow should be ascertained by gauging; it is best to do this over as long a period as possible.

In England the Local Government Board's regulations are so severe in connection with bacterial systems that the cost is much enhanced. The conditions are:—(1) Each set of filters (i.e., both coarse and fine) must be of sufficient capacity to contain the normal dry-weather flow for twenty-four hours. Coarse grain beds can hold 25 per cent. sewage and fine beds 33½ per cent. This means, taking an eight-hour cycle, that the beds must be large enough to deal with three times the dry-weather flow, i.e., one volume normal, two volumes storm water. (2) Land has to be obtained at the rate of one acre per 1,000 population to take the effluent. (3) Storm water filters of some coarse material, such as clinker, burnt ballast, or gravel, must be provided in addition to the above to treat a further quantity of storm water equal to three times the dry-weather flow. Instead of filters a special area of land can be set apart to receive storm water.

The future of bacterial treatment and the future of sewage disposal are, I believe, one and the same thing. A Royal Commission is investigating the subject at the present moment and it is hoped the report, when it appears, will definitely state that, subject to certain conditions as to dimensions of tanks, beds, &c., bacterial systems may be adopted without subsequent land treatment. The report of the invaluable Manchester experiments, the results of bacterial treatment at Barking and Crossness, and the undoubted success of the installations on various systems now at work throughout the United Kingdom and abroad, warrant the inference that bacterial treatment is universally applicable. Not only is the cost less, but the results are far superior to any obtained by the use of chemicals, and the sludge difficulty does not arise. Further, as the nitrates derived from the nitrogenous substances are in such form and in such quantity as to be readily assimilated by plant life, it may be that in time to come this manurial value will be utilised by extensive irrigation. At any rate, it will not be necessary to flood the land at unsuitable seasons, nor will there be any risk of making it sewage-sick.

The County Council Buildings at Stafford are to be extended. Messrs. Wilcock, of Wolverhampton, have secured the contract for £5,199.

HOLBORN TO THE STRAND.

THE Improvements Committee of the London County Council has decided to advise the Council to invite designs from eight leading architects for the elevation of the buildings to front the northern side of the Strand, and the northern and southern sides of the new crescent road as far as the junction with the main street. Four of the architects should be nominated by the Council, and four by the Royal Institute of British Architects, and the premium to be paid to each architect for the designs should be £150. The total sum to be expended would, therefore, not exceed £1,200. The Committee was strongly of opinion that it would be much better for the Council to invite designs from merely eight selected architects than to have an open competition, for which the leading professional men would not send in designs. Among the conditions mentioned in the form of invitation it would be stipulated that the buildings may be 80ft. high from the level of the pavement; it may be desirable to treat the centre block of the crescent-shaped island as devoted to one building, the streets at the flanks of it being approached by arcaded footways with steps up towards the curved street on the north side, and by a carriage road from the end leaving the Strand; the materials to be employed in the elevations to be of stone, marble, or granite. No other materials would be admissible; the style suggested was Palladian freely treated and of a simple character, it being borne in mind that the buildings may be intended for commercial purposes; and the designs, which would be publicly exhibited, are to be sent in, addressed to the architect to the Council, within six weeks of the date of nomination by the Institute and the Council respectively. The decision of the Council with regard to this recommendation will be announced next week.

ART IN FRANCE AND ITALY.

ART in France is under the care of a special Department of the Ministry of Public Instruction, and is encouraged by an annual expenditure of from 15,000,000fr. to 18,000,000fr. (about £720,000). The ruling principles of the Direction des Beaux Arts are to leave to artists their entire freedom of conception and execution, and, further, to advance in every possible way the application of art to industry. The present Director of Fine Arts is M. Henry Roujon. There are in France eleven State schools of fine arts or decorative arts, but they are naturally of various degrees of importance. The chief one is the Ecole des Beaux Arts of Paris, which is one of the most important establishments of higher education in France and is much appreciated by foreigners because it is without a rival in the world. The other French State schools are the Schools of Fine Arts at Bourges, Dijon, Lyons and Algiers, the Schools of Decorative Arts at Paris, Aubusson, Limoges and Nice, the National School of Drawing for Girls at Paris, and the School of Industrial Arts at Roubaix. At the Ecole des Beaux Arts in the Rue Bonaparte, Paris, drawing, painting, sculpture, architecture and engraving are taught. The method consists of, first, lectures on the different branches of art; and, second, practical teaching. The professors of this institution include such men as Bougereau, J. P. Laurens, Gerôme, Bonnat, Gustave Moreau in painting, and Barrias and Falguière in sculpture. Candidates must be between fifteen and thirty years of age, and must produce a document from some competent person stating that they are capable of undergoing the test. Foreigners are admitted, but they must produce a letter from their ambassador, minister, or consul-general. The examinations for admission take place in March and July of each year. The mission of the Ecole Nationale des Arts Décoratifs de Paris is to form artists and artisans for the artistic and decorative industries. Without going into details regarding the Paris Special

School of Architecture or the Girls' Drawing School of Paris, which chiefly turns out teachers, and many other special establishments, the foregoing amply shows how well both the fine and the industrial arts are cared for by the French Government.

The art-teaching institutions of Italy may be divided roughly into two classes: (1) fine art academies, and (2) arts and crafts schools. The academies, which date chiefly from previous centuries, are confined to the teaching of drawing, painting, sculpture, architecture, and some minor branches of the fine arts. They exist principally in the larger cities, and their cost is proportionately very much higher than that of the arts and crafts schools. The latter are officially known as schools of design and modelling, schools of art applied to industry, schools of art and trade, and schools of industrial design. Their foundation is almost exclusively the work of modern Italians; that is to say, they owe their existence to the stimulus given to education and culture by the national Government. The great majority of the schools are free, but in some cases a nominal fee for registration is charged, varying from 5 francs to 20 francs a year. The cost of maintenance of the schools falls on the State. Altogether 1,511,000 lire (about £30,000) of public money is annually spent in Italy for the promotion of art and art handiwork. Of this total nearly 928,000 lire is paid for keeping up 146 schools of arts and crafts, in which 594 professors are employed to give instruction to some 16,000 pupils. As subsidies, 583,000 lire is spent on 23 fine art academies, which employ 187 professors to teach 3,515 students. These figures do not include Piedmont and a part of Lombardy. More than £26,000 is laid out annually as income derived from legacies and bequests. If the total sum of £86,000 seems small, it must be remembered that a large number of the schools of arts and crafts cost for maintenance less than £40 a year. Some large arts and crafts schools cost the State as much as £3,200 a year, but the average is only £250. The average for the fine art institutions is slightly over £1,000 a year, exclusive of the funds derived from the endowments of these institutions. The school of architecture at the Venetian Institution of Fine Arts (which dates from the thirteenth century) comprises the study of the history of architectural styles, the composition and modelling in clay of architectural ornaments, the internal decoration of buildings, perspective and water-colour drawing, with a course of lectures on aesthetics as applied to architecture. The conditions for admission to the Institute are: To be more than twelve years of age, to have passed the fourth Italian standard of elementary education, and the payment of an annual fee of thirty lire (£1 3s.). The number of professors is thirteen, and the total cost of the Institute to the State is £2,100 a year. The foregoing is a synopsis of two interesting articles which appeared recently in the "Morning Post."

"Bills of Extras" were dealt with by Mr. G. H. Oatley, F.R.I.B.A., at a recent meeting of the Bristol Society of Architects. A fruitful source of extras was very often the inability of the client to clearly formulate his requirements and supply his architect with proper particulars; another cause was the very inadequate time allowed, in these days of rush and hurry, for the preparation of the contract. Another, and perhaps the chief cause, was the possibly natural attempt of the builder to obtain as large an amount as possible for so-called extra work, owing to a misreading or misunderstanding of the contract; but this was confined to the less reputable class of builders, and arose, chiefly, when the original contract was taken at a low figure.

WE WANT A SHILLING for the B.J. Shilling Fund from every architect, draughtsman, builder, clerk of works, foreman and workman who reads the BUILDERS' JOURNAL. Have you paid yours?

Under Discussion.

A Doctor on Dwelling-Houses.

Dr. G. Vivian Poore, M.D., F.R.C.P., recently delivered a lecture on "The Dwelling-House from a Doctor's Point of View" at Carpenters' Hall. The first consideration was—Where to live, in town or country? He emphatically favoured the latter, and instanced the fact that out of every 100,000 persons born in the United Kingdom an average of 80,000 to 85,000 survived infancy; whereas in the township of Manchester the total was only 60,000. The expectation of life in a healthy country place was fifty-two years, but in Manchester it was only twenty-eight years. In the neighbourhood of London, taking 1,000 as an average, the mortality figures for 1893 gave 1,215 for the City of London, 1,592 for the Strand, 704 for Lewisham, and 673 for Hampstead, showing conclusively the advantage of the country as a place of residence. Dr. Poore next dealt with the question of soil, and put gravel and sand first, chalk second, and clay last. The subject of frontage was an important one, he added. A south-east frontage was the best, as it afforded sunshine during some parts of the day to every side of the house. Sunlight was most essential to health, and the question of frontage was all too little considered. In regard to building material, brick or stone was necessary for towns, but the lecturer strongly advocated wood for small country houses.

Renaissance Plasterwork.

At a meeting of the Edinburgh Architectural Society held on Wednesday last Mr. Harold Tarbolton lectured on the "Plasterwork of the Renaissance and its Subsequent Phases." He said that in the reign of Henry the Eighth there was a large influx of craftsmen from Italy and Germany, and it required about a hundred years for the fusion of the foreign and home ideas. Some fine examples of this period were recorded in the Palace of Nonesuch and the Broughton Chapel. After the death of their patron, Henry the Eighth, the Italians became unpopular, partly on account of religion, and left the country. In the reign of Elizabeth large numbers of German and Dutch craftsmen settled down in England. Examples of the German style are to be found in many Elizabethan mansions, and are noted for their intricacy of detail. The East of Scotland is very rich in old plasterwork, in which there is strong evidence of German, Dutch, and French influence. Inigo Jones introduced the German style into his work to a great extent. Mr. Tarbolton made a few remarks upon the methods of work in plastering. In earlier years the lime was tempered by burial in the earth for several years before being used, and it is more than probable that some ingredient was also added for this purpose. Most of the work was done *in situ* and not cast. The best material at the present time for executing plasterwork *in situ* was Parian cement mixed with a small quantity of sand. In conclusion the lecturer said that it was most important that the designer should have a thorough practical knowledge of the work, and should be capable of handling the tools, as the effect of good craftsmanship was often lost in bad design.

Dirty Streets.

"The Insanitary Condition of London Streets" was the subject of a paper read last Wednesday evening before a meeting of the Sanitary Institute, held at the Parkes Museum, Margaret Street, W., by Mr. W. Nisbet Blair, engineer and surveyor to the St. Pancras Vestry. Mr. Blair said that he was not likely to meet with contradiction in making the assertion that our streets were frequently in a very uncleanly condition; though whether that necessarily meant an insanitary condition was at any rate open to argument. He held that for a time it did not, for, until decomposition commenced, the multiplication of bacterial life did not make any progress. It was true, no doubt, that the question of street cleansing

was only made difficult by reason of the immensity of the areas and the quantities of materials to be dealt with and the consequent expenditure; but while we must be limited to some extent by the question of economy, it must not be thought that no attempt was being made towards improvement, even at a somewhat increased cost, and he had heard it admitted many times that the condition of our streets was now immensely improved upon what it was ten or more years ago. Mr. Blair proceeded to describe the methods and cost of the work in St. Pancras, saying that the cost amounted to £284 a mile for a year, 200 sweepers being employed and over 84,000 cubic yards of material being removed, which would work out at 980 cubic yards per mile, or close upon 2,000,000 cubic yards per annum for the whole of London. With regard to the snowfalls in January, 1895, St. Pancras Vestry on several days engaged 1,000 men or more in the removal of the snow, and the total cost incurred was £2,472. In conclusion, Mr. Blair's opinion was that so long as horse traction continued we should be unable to keep our streets in a condition which would escape complaint, for, besides the droppings distributed continually, there was also the ultimate graving and watering, the latter natural or artificial, necessary to prevent the slipperiness or to lay the dust. The grinding up of all this by passing wheels ensured plenty of work for the scavenger, and until motor traffic became general he feared that no material improvement in the cleansing of our streets, coming within a reasonable limit of cost, could be secured.

A Lawyer on Workmen's Compensation.

Workmen's compensation, in all its legal bearings was reviewed on Thursday last by Mr. A. H. Ruegg, Q.C., before the members of the Solicitors' Managing Clerks' Association. Mr. Ruegg said that in every civilised State a citizen had a right to personal security, and it was accepted as a duty that we should so act and so use our rights that no injury should be inflicted upon another. This became a common law obligation until the industries of the country assumed gigantic proportions. It was not until 1837 that the doctrine of common employment was raised in a case relating to a butcher's boy. The learned gentlemen went on to speak of the many erratic decisions by County Court juries when dealing with cases under the Act of 1880. He had seen £125 given for an injury to a little finger, while £25 had been awarded for the loss of a right leg. He suggested that it would serve a useful purpose if a County Court judge were given power to invest money awarded as damages, or to pay it in instalments—a system which found favour in both Germany and Austria. Dealing with the Compensation Act passed by the present Government, Mr. Ruegg remarked that it was based on the German system, although by no means identical with it. The German law grouped the different trades, making them a sort of mutual insurance company. The Act of 1897 was unpalatable to many employers, and, so far as he was aware, it was not agitated for by workmen or trade unions. As a matter of fact, the provisions were too novel to this country to be applied to trades beyond those regarded as dangerous. Dealing with the anomalies of the Act, the lecturer pointed out that if a carman fell off his load in the factory yard and was killed, his dependents would be entitled to compensation; yet if he was killed in a similar way some distance off, no compensation could be recovered. Again, before a workman engaged on a building could recover, the structure must be 30ft. high. A dock was a factory, and, but for the fact that various parts of the Factory Act were incorporated in this measure, a ship would be a factory also. Up to the present there had been one hundred appeals, and the number was not excessive considering that it was a new Act, founded upon untried principles, and that many industries were necessarily on the border line between those included in the Act and those excluded. In Germany the appeals in the High Court averaged 10,000 a year. He was convinced that sooner or later the Act would be extended,

so as to include all industries. However, the principles the Act embodied ought to have a fair trial, and let them all hope that it would be productive of nothing but good to the workmen of the country.

Old Towers at Holyrood Palace.

At the monthly meeting of the Society of Antiquaries of Scotland held last week, Mr. John Sinclair, F.S.A., Scot., read a paper on the towers of James the Fifth at Holyrood Palace. As no thorough exposition either with respect to their characteristic exterior or their intricate internal structure had yet been given, he had been induced by the interest of the subject to make an attempt to supply the deficiency. After alluding to the description by John Young, "Somerset Herald," of the palace in 1503, and noticing the entries in the Lord High Treasurer's accounts, he inferred from these, and from a reference in 1515 to the Auld Tower of Holyrood, that there was good ground for attributing the oldest part of the structure to James the Fourth. From other circumstances it was inferred that the towers shown in the views of Hollar and Gordon of Rothiemay were the work of James the Fifth, a conclusion borne out by an elaborate examination of various points in connection with their external and internal construction, and their relation to other parts of the building as it existed in the time of Mary Stuart. After tracing the changes and extensions effected by Sir William Bruce, he concluded, by giving a minute description of the interior arrangement of the oldest towers, the sole survivors of the original palace.—In another paper, Mr. Alexander Munro described a rude stone slab in the moorland at Strathly, Sutherlandshire, which bears on one face, very clearly incised, a cross of peculiar form, nearly 3ft. long. The summit and the base, as well as the two arms, terminate in circles formed by the expansion of the two outer lines of the cross. In the centres of the four circular expansions are hollows or cups of about 3in. diameter, and in the centre of the cross are traces of a fifth cup. If these could be supposed to represent the cups and rings of the Pagan sculptures on rocks and stones, we might be justified in assigning to this cross a very early date; but whether it might be assigned to the seventh century or to the thirteenth, it was a cross of a form unique in Scotland, and therefore of much archaeological interest.

A Gladstone Memorial Bust was unveiled on Wednesday last in the Debating Hall of the Oxford University Union Society. It has been executed by Mr. Onslow Ford, R.A.

Improvement Scheme at Bath.—By Lampard's Buildings improvement scheme it is proposed to pull down a number of the old houses from Julian Road up towards Landsdown Road, Bath, to form a new road 30ft. wide and build thirty-six working-class houses. The estimated cost is £14,000.

"Houses for the Working Classes in Urban Districts."—Mr. B. T. Batsford will publish shortly a volume with this title, by Messrs. S. W. Cranfield and Potter, of London, Associates of the R.I.B.A., dealing with single and double tenements and other terrace houses suitable for labourers, mechanics, and other weekly wage earners.

A new Higher Grade Board School at Birmingham has been built in Wright's Lane, Old Hill, from designs by Messrs. Meredith and Pritchard at a cost of £9,056. Accommodation is provided for 348 children, besides which the infants' school (which is not yet completed) will accommodate 340. Mr. G. Cockin, of Old Hill, was the builder.

"A Parish Church" was the title of a lecture delivered by Mr. C. Hodgson Fowler, F.S.A., before the Sheffield Society of Architects and Surveyors last week. He mentioned that, in the thirteenth century rebuildings and enlargements took place all over the country, and it was then the old nave and chancel arrangements began to be extended by the introduction of aisles. In the earlier instances, the aisles were simply built up outside, the nave walls were taken down, and arches connecting them with the new parts thrown over.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"A dexterous hand without a head to guide it is a blind tool; a head without a hand to realise its wishes is an impotent nothing."—CLAUDE BERNARD.

Army Engineering.

AN army has always several hand pumps for lifting and forcing water. These cost £17 each, and, in addition, there is a supply of piping. But even a stream cannot always be found. Lord Methuen's column on its march to the Modder River found the absence of water courses as trying almost as the obstacle set up by the Boer forces, and the river was desecrated with delight. So also with Buller's force on Spion Kop. The column in Natal has the usual service plant for boring artesian wells. It includes a hand pump with a 15in. barrel of 2½in. internal diameter, costing alone £76, with 4in. iron tubes, making up a total length of 100ft. The whole plant cost £140. With regard to pontoon work, it is somewhat remarkable that here there has been little change since Caesar's time; greater strength of pontoons may be achieved, but the method does not differ. The British pontoon structure is an expensive business. A boat with ten rowlocks costs £75, and a bipartite, meaning a boat in two pieces, with sixteen rowlocks, and locking levers, &c., costs £98. Baulks of timber and bridging trestles are also supplied. These trestles sometimes run up to £29 or £30. The necessity for reliable strength is a reason for the great cost of pontoons and trestles. From this it will be understood that there are a large number of non-combatants in the army—mechanics of every kind; and it is worth noting further the cost of their tool chests. For two regimental bricklayers and masons the cost of equipment is £5, for three carpenters £7 10s., for wheel and saddle-tree makers £11 each, for armament artificers £27 each, for collarmakers and saddlers 4 guineas, for farriers and smiths 4 guineas; while the equipment of the telegraph mechanics costs £110, including, as it does, a lathe with a 3ft. bed and 3½in. centres. This latter alone is worth £18. There is also a portable forge, which costs £160.

Incongruities in Glasgow Cathedral.

A CORRESPONDENT to a local paper points out that it is about time some of the incongruities in Glasgow Cathedral were removed. "In the first place," he says, "I would refer to the miserable array of varnished wooden benches—the property of the Town Council, I understand—which confront the eye of the visitor as he enters the choir. Why fill up the grand old Bishop's beautiful choir with such abominations? All the bases of the Gothic columns are hidden from view by the disfiguring woodwork, to say nothing of the general loss of effect by their presence there. What I would suggest is to take out all the wooden benches and re-seat the choir with chairs similar to those in that part of the building usually known as the Lady Chapel. The second point which is worthy of public consideration is the wooden erection which is tacked on to the eastern face of the stonework of the rood screen, and which serves at present as a platform for the vocalists who assist in the service. This erection, I suppose, dates from the same period as the wooden benches. Take it away and restore the rood screen to something like its original condition, and accommodate the choir in another part of the building. The last point I would draw attention to is the position of the fine memorial organ which enters so largely into the really excellent Scottish church services which are held every Sunday. Why was the builder of the instrument permitted to spoil the internal lines of the building by allowing the organ case to jut out from each wall in the manner it does? Apart from the unsubstantial appearance it has, it is not at all in keeping with the architecture, and could very well have been constructed in such a way as to add to and not detract from the effect of

the fabric as a whole. The stained-glass work in the building I will refrain from criticising. It has long ago been relegated to its proper position by those competent to judge."

Jacobean Gables.

THE Jacobean gables shown in the accompanying illustration are situated in the oldest part that now remains of Cockfield Hall, Yoxford, Suffolk, the seat of Sir Ralph Blois, Bart. From its general character the house must have been built early in the seventeenth century in the reign of James the First. The finials surmounting the gables, and on the parapet between the gables, have a very rich effect, especially as they are all slightly different in their decoration. This house has lately been restored, and a great part of it entirely rebuilt; but it is gratifying to note that this part has had nothing done to it beyond scraping, the red brick having been covered with frequent coats of lime-wash. The part that was pulled down was not very interesting externally, but there was concealed from the casual observer a very beautiful old hammer-beam roof built principally of sweet chestnut. This, unfortunately, was entirely destroyed and sold to be broken up for firewood or some such purpose. The ends of the hammer-

JACOBEOAN GABLES, COCKFIELD HALL.
DRAWN BY WILLIAM BROOKE.

beams (four only of which were visible) were most quaintly carved with grotesque faces of Gothic character. This clearly was the roof of the old banqueting hall. When removing the plaster of the walls below, the old oak stud work was revealed and in the centre of one end was a very quaint Gothic spandrel, which was over the door that led probably to the kitchens and offices. Our illustration is from a pencil drawing by Mr. William Brooke.

Ruskin's Working Man.

AS has been often stated, some of the later writings of John Ruskin, notably "Fors Clavigera," were more or less inspired by a certain working man. Mr. Edward Sutton writes to the "Nottingham Daily Guardian" to tell all about this man, whom he knew well.—Mr. Thomas Dixon was a master cork-cutter at Sunderland. He was a man of but very moderate attainments, not being distinguished beyond others in his own particular sphere of life. But there was a great fascination about him, and in conversation and manner he was inspiring, alluring, and helpful to every one who sought his society. The letters published under the title of "Fors Clavigera" were in every instance, when penned, forwarded to Mr. Dixon for his approval and comment; and were afterwards moulded and considerably reshaped in accordance with his remarks on them. Ruskin revolted against the doctrines and economists of the now discredited Manchester School, and as a consequence he wrote

and similarly submitted other letters, published under the title of "Time and Tide by Wear and Tyne: or Lettersto a Cork-cutter of Sunderland." But Ruskin was not the only one who thus honoured Mr. Dixon—Carlyle, Tennyson, Walt Whitman, Emerson, Tom Taylor (himself a native of Sunderland), Rossetti, W. B. Scott, Clarkson Stanfield (another townsman), Holman Hunt, Boehm, the sculptor, Mazzini, Orsini, Gavazzi, Garibaldi, and a host of others, in various walks of life, were similarly brought into requisition by him. His knowledge and judgment of art and literature were wonderful, varied, and extensive; and his love of both so deep and surpassing as to make his opinion and dictum invaluable and widely sought.

A Museum of Great Marbles.

THE separate museum constructed in Berlin to receive the great marbles from Pergamum, of which during the last seventeen years the major part has lain on the ground, practically unseen, in the ground-floor galleries of the present building, is now fast approaching completion. It contains a faithful reconstruction, on the scale of the original, of the vast open-air altar on the Acropolis of Pergamum, round the podium and the sides of which ran the gigantic frieze in high relief with the Battle between Gods and Titans. The chief motives of this have already become familiar all over Europe through the casts which the museums have obtained through the generosity of Berlin. Very important sections of the frieze, which is 8ft. in height and was 460ft. long, having been preserved, the effect of the altar, as thus in a great measure reconstituted, should be stupendous. This Asiatic Greek art, dating late in the second century B.C., stands in its demonstrative and rhetorical passion wholly apart from anything produced during the great periods, that is, the fifth and fourth century B.C. The technical skill displayed, the easy triumph over all difficulties of workmanship, is nothing short of astonishing. All the same, there is in these Pergamenean sculptures an element of over-emphasis and dramatic passion torn to tatters which amounts almost to vulgarity. And this is the last word that the lover of antiquity would like to pronounce in connection with Greek art.

Two Interesting Models.

ON Friday last a representative of this journal inspected two models that have been made for the Metropolitan Asylums Board by Mr. John B. Thorp, of the London Drawing and Tracing Office, 98, Gray's Inn Road, W.C. One is of the Brook Hospital, Shooter's Hill, S.E. (T. W. Aldwinkle, architect), about which it will be remembered, some discussion took place a short time ago with reference to the large expenditure for extras. The other model is of the North-Eastern Temporary Hospital at Tottenham, N. (A. and C. Harston, architects), which was built some years ago to meet an epidemic of scarlet fever. It comprises about forty wooden buildings, and was put up in the remarkably short space of seven weeks. Both models are about 6ft. square, and are made to a metre scale (as they are intended for the Paris Exhibition), which works out at about 16ft. to the inch. Their cost has been £400 altogether—£300 for the Brook Hospital and £100 for the other—and they are ingeniously constructed of wood and cardboard, billiard felt being used to represent the grass, and stained sponges the trees; the latter are very effective. The utility of models of large public buildings need hardly be emphasised, as this has been proved in many instances. The excellent manner in which they show how the buildings will look when completed well repays their cost. Of course, the trained architect can without difficulty realise from the study of plans and elevations what the completed building will be like; but this is not the case with the general public and those who generally form the building committees of public bodies. The existence of a model would assist their judgment and often prevent serious mistakes.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Book on Ivory Carving.

WEST KENSINGTON, W.—H. P. writes: "Where can I obtain a book on carving or working ivory?"

No book has been published on this subject, but there are a number of references in "Workshop Receipts" (second series), which costs 5s., and is published by Spon.

Constructing a Skittle-Alley.

CATFORD.—S. T. writes: "I should be glad if you could inform me how to construct a skittle-alley, stating dimensions, lighting, &c."

A single skittle-alley should be 40ft. long and 12ft. 6in. wide, but a double alley need only be 21ft. 6in. wide in all, being divided by a diagonal line or partition so that each court is 9ft. wide at the service end and 12ft. 6in. wide at the other. It should be perfectly level, with a concrete bed either floated in cement or covered with asphalt, and with a cleft wall right round to retain the balls within the court. A roof of some sort should be provided. A single alley should be supplied with a channel for return balls along one side, or both, laid to slope downwards to the service end.

G. A. T. M.

Rateable Value of L.C.C. Tenements.

GRAYS.—R. W. writes: "In connection with the reply in your issue for January 31st last, on 'Percentages and Property Valuation,' it would be interesting to know how the rateable value of the tenements erected by the London County Council compares with their gross rental, seeing that you state at the close of your interesting article on 'The Housing Problem' (issue January 3rd) that 'In London over 55 per cent. of the gross rental is absorbed in the expenses of management, repairs and the like, while in Liverpool 40 per cent. has been allowed.' Can the London County Council claim a larger allowance for outgoings than private owners?"

It does not appear that the County Council has any such monopoly. Section 4 (2) of the Customs and Inland Revenue Act, 1891, directs that, in the case of a house used for the sole purpose of providing separate dwellings at an annual value not exceeding £40 for each dwelling, the Commissioners shall confine the assessment to the annual value of the house, exclusive of every dwelling therein, of an annual value below £20. This may account for the low rateable value of the tenements in question.

G. H. B.

Architects' Pupils and Overtime.

BRISTOL.—ADMIRER writes: "A youth was article at a premium to an architect and surveyor, nothing being said on either side about wages. The office boy was discharged, and the pupil had to take over his duties, being told that it was not usual to pay wages to pupils and that he must do 'overtime' without remuneration. This seems to me very unfair, and I should be glad to know what is the rule as to remuneration for 'overtime.'"

This appears to be a case for the intervention of parent or guardian. The pupil should not be called upon to work "overtime" for the performance of the duties of an office boy, nor for any other purpose save upon emergency, when most principals would ask for it and most pupils would comply. At the same time, remuneration is rarely offered for such compliance, except possibly a little extra holiday when the pressure is released. If the R.I.B.A. form of articles has been used, the principal would be bound to allow his pupil sufficient time and opportunities for study, and this

clause might well be used to prevent any undue employment of the pupil beyond the regular office hours. It is by no means bad training for a pupil to act as office boy for a few months at any rate, however much it may offend his dignity.

G. A. T. M.

Liabilities for Errors in Tenders.

FOLKESTONE.—CONSTANT SUBSCRIBER AND READER writes: "A short time ago I tendered to an Urban Council for providing and fixing a cleft oak fence, and my tender, being the lower of two, was accepted. Before signing the contract I discovered I had made a clerical error, having divided the lineal feet by nine instead of three, to bring it to yards lineal. I wrote to the Council, explained the mistake, and requested that my tender be withdrawn. They replied that they should not release me; but later wrote me a letter stating that they were prepared to acknowledge the error, and, without prejudice, would offer me half the difference of the extra cost involved. As I should lose by this, will you kindly say whether they can legally compel me to carry out the work. I would add that no quantity of fencing was stated in my estimate nor had the Council's surveyor shown it on the plan or mentioned it in the specification."

If the value or amount of the work tendered for exceeded £50, the acceptance of the tender in order to constitute a binding contract should be under seal (Public Health Act, 1875, section 174, sub-section 1; *Kingston-on-Hull Commissioners v. Petch*, 10 Ex. 610; *Dartford Guardians v. Trickett*, 59 L. T. 754; *Hudson on Building Contracts*, 2nd Edn., Vol. 2, page 121.) If so, our correspondent can refuse to carry out the contract, but otherwise he cannot. If the quantity of fencing was indefinite so that the value or amount of the work might, or might not, exceed £50, then it would not "exceed £50," and our correspondent could not refuse to carry out the contract (*Eaton v. Basker*, 1881, 7 Q.B.D. 529).

H. P. B.

Local Authorities and Drainage.

CREDITON.—JUSTICE writes: "A local authority adopted the whole of the Public Health Amendment Act, 1890, but they served notice on A under the Public Health Act, 1875, 38 & 39 Vic. c. 55, section 94 and schedule 4 (form A.)—and under no other sections or provisions of Acts—to take up the old and lay . . . pipe drain . . . with inspection chambers and an interceptor near sewer.' There are no by-laws relating to sanitary work adopted by the local authority. A's drain also takes off the sewage from the w.c. which belongs to the adjoining house occupied by B. The local authority knew the facts, but requested A to do the work forthwith. A has had the work done at his own expense. (1) What is A's remedy? (2) Is B liable to A for part of the expense? (3) Can A compel the local authority to reimburse him for the whole or part of the expenses? (4) Could the above notice under the Public Health Act, 1875, be amended or made good by any court of law, so that the notice shall be applicable under the Public Health Amendment Act, 1890, or under any other Public Health Acts? (5) In the event of a lawsuit, would the cause be limited to the specific Public Health Act, 1875, and the section under which the notice was served, or could other Acts of Parliament be introduced by either party? (6) Would it be expedient or an expensive matter to lay the above facts before the Local Government Board for redress?"

(1) A's remedy (if any) appears to be against the local authority for B's share of the expense. A should consult a solicitor. (2) B is not liable to A, but to the local authority. (3) Perhaps A might recover part of the expense from the local authority. (4) There would be no need to amend the notice, because A has only done what he and B could be compelled to do under section 19 of the Public Health Act, 1890. (See *Self v. Hove Commissioners*, Div. Ct. [1895] I.Q.B. 685.) (5) The case would be decided under any Acts of Parliament in force. (6) It is not likely to do good, though it might not be expensive. G. H. B.

How to Become a Student of the R.A. Architectural School.

EALING, W.—H. W. S. writes:—"I should be glad to know how one may become a student of the Royal Academy Architectural School."

No sculptor or architect is eligible for admission to the schools of the Royal Academy who is more than twenty-five years of age on the date fixed for the delivery at the Academy of works for probationership. All instruction in the Academy is gratuitous, the students providing their own materials. Applicants for admission must obtain from the Registrar, through the written request of any member of the Academy, or other artist or person of known respectability, a printed form, to be filled up and delivered at the Royal Academy, together with a certificate of birth and the required specimens of ability, on or before January 1st or July 1st. Architects must also send a certificate from an architect member of the Royal Academy, of the Royal Institute of British Architects, or any other public institution for teaching art and science, certifying that the applicant has followed up the study of architecture and architectural drawing, and has acquired a fair degree of proficiency. The specimens required from architects are:—

(1) A geometric elevation of some part of an existing building (which may be copied from published drawings or prints) in which some part of the ornament or other features shall be drawn in freehand; (2) geometric elevations of the Doric, Ionic, and Corinthian Orders, with their entablatures complete, to $\frac{1}{2}$ in. scale, the columns to be 2ft. high; (3) an original perspective sketch in pencil of an existing building, or part of a building, on a quarter-sheet of Imperial paper; and (4) a drawing of a piece of architectural ornament from a cast, shaded in pencil or chalk, or tinted, and of the size of the original. All the drawings required must be on paper, and unmounted. The above required specimens of the applicant's ability will be submitted, within two weeks of the date of their being sent in, to the Council, who will select a certain number as probationers to compete for the vacant studentships. Notice of their admission as probationers will be sent to the successful applicants, and they will be summoned to attend on a fixed day at the Academy and there execute the following works:—(1) A geometric drawing from memory only of one of the Orders, to $\frac{1}{2}$ in. scale, the Order and height of the Order to be fixed by the Council, and no book or other aid allowed, to be done in two hours, from 6 p.m. to 8 p.m.; (2) a drawing from a cast, the size of the original, to be done in seven evenings of two hours each, 6 p.m. to 8 p.m.; (3) a geometric elevation (with or without a plan) of a building, or some part of a building in London, to be done from the probationer's own notes and measurements, taken from the building itself, in two evenings of two hours each, 6 p.m. to 8 p.m., the notes and measurements to be submitted to the Council; (4) and two studies in outline, each on a quarter Imperial sheet of paper, of two of the principal casts (to be selected by the master of the school) in the architectural school, to be done in two evenings of two hours each, 6 p.m. to 8 p.m. The successful competitors will be admitted students of the Royal Academy for three years. At the end of this time, subject to the fulfilment of certain conditions and the passing of an examination, students will be admitted for a further period of two years.

Wallpaper Combination.—The Association of Wallpaper Manufacturers, after working jointly since September 30th last, is now preparing a prospectus, and an issue of capital (probably £8,000,000) will be made shortly.

Portsmouth Technical Institute.—At a meeting of the Portsmouth Town Council, held last week, a resolution proposing to rescind the motion for erecting the new technical institute on the Mayor's Lawn was lost. This matter was referred to at length on p. 400 of our issue for January 31st last.

Keystones.

Mr. William Ewart Lockhart, R.S.A., died recently at the age of fifty-three.

The **Ruskin Union** held its first council meeting on Saturday. It already has 103 members.

Mr. E. A. Chattock, of London, has been appointed electrical engineer to the Bradford City Council at a salary of £500 a year.

A new **Board School at Auldhousie, Glasgow**, has been built from designs by Mr. D. Barclay, architect, Glasgow. It accommodates 100 scholars and has cost £1,500.

A new **Technical School at Stratford-on-Avon** has been built from designs by Mr. Arthur Flower, architect, at a cost of £1,600. The art studio is 40ft. by 27ft.

Builders' Heavy Failure at Stamford.—The firm of Hinson Brothers, builders, Stamford, has filed its petition. The liabilities are about £12,500, and the assets about £6,500.

Science and Art in Cornwall.—In Cornwall last year there were sixty honours passes in science and art (twenty of them first-class), as compared with twenty-seven for the previous year.

Placards at Whitehall.—The Office of Works has decided not to allow posters to be placed on the hoardings around the huge sites in Whitehall and Parliament Street on which the new Government offices are to be built.

Royal Scottish Academy.—Mr. Alexander Roche, A.R.S.A., and Mr. John Henry Lorimer, A.R.S.A., have been elected to full membership of the Royal Scottish Academy in the place of Mr. Alexander Fraser and Mr. John Smart, both deceased.

Newport (Mon.) Technical Institute.—It has been decided to proceed with the purchase of 3,700 sq. yds. of land in Clarence Place, near Newport Bridge, for the erection of a technical institute. Lord Tredegar is the owner of the land, and he has agreed to sell it for £2,571.

New Lock at Teddington.—It has been decided to construct an additional lock at Teddington on land adjoining the present lock. This new lock will be the largest on the Thames. Its length between the gates will be 650ft. and its width 25ft. Its estimated cost is £20,000.

A South African Memorial.—Mr. John Tweed, the well-known sculptor, is making considerable progress with the fourth and final panel of the gigantic memorial which Mr. Cecil Rhodes proposes to erect near the Shangani River to Major Alan Wilson and his ill-fated party. This panel will contain nine life-sized figures.

The new High School for Girls at Kirkham, Preston, which the Worshipful Company of Drapers has offered to build will be of brick with stone facings, and will be surmounted by a small tower or belfry. The building will be two storeys high, and accommodation will be provided for 100 scholars. The total cost is estimated at £4,000. The plans, will shortly be submitted to the Charity Commissioners.

A new Infectious Diseases Hospital at Braintree was opened last week. The buildings are situated on high ground just outside the town, on the Cressing Road, and consist of the hospital proper, with two wards divided by the nurses' duty-room, caretaker's house detached, and outbuildings, comprising mortuary, washhouse, disinfecting chamber, and ambulance shed. The buildings are of red brick and slated, and cost about £3,000.

The Memorial to Rosa Bonheur which is to be erected in the gardens of Fontainebleau will take the form of a bronze statue of a bull upon a stone plinth, and will be about 14ft. high. The plinth is to be decorated with four panels in bronze, one a portrait in bas-relief of the late painter, and the other three will be modelled upon her celebrated works. The cost is to be defrayed by M. Gambard, Spanish Consul at Nice.

Extensive additions to the First Avenue Hotel, Holborn, are about to be made according to designs by Mr. L. H. Isaacs and Mr. H. L. Florence, architects, of 3, Verulam Buildings, Gray's Inn, W.C.

A Great Work.—Upon the development of Hong Kong Harbour the Government is about to spend £17,000,000. A contract for extensive alterations has been placed with Messrs. Punchard, M'Taggart, Lowther and Co., of Cannon Street, E.C.

Broughton-in-Furness Church.—At the Carlisle Consistory Court on Wednesday last permission was granted for the erection of a new church tower and peal of bells which Lord Cross is presenting to the parish of Broughton-in-Furness.

The Annual Dinner of the Staff of Mr. William Griffiths, stone and granite merchant and pavior, of Hamilton House, Bishopsgate Street Without, E.C., was held at the Great Eastern Hotel, Liverpool Street, E.C., last Saturday, Mr. Griffiths presiding.

Amalgamation of Welsh Slate Quarries. A scheme is being prepared for the formation of a syndicate to amalgamate most of the Carnarvonshire and Festiniog quarries under a working agreement with the owner of the Llanberis and Penrhyn quarries. The capital will be £1,250,000.

Taunton's new Technical Institute.—The new technical institute which has been erected in Corporation Street, Taunton, was formally opened last week. The building, which adjoins the municipal buildings, has a frontage of 60ft. and comprises electrical and physical laboratories, and the necessary workshops, together with a good-sized lecture hall and ordinary room.

Dissolution of Partnership.—The partnership hitherto subsisting between John Batcheler and Charles William Leopard and carried on by them under the style of Haines and Co., at 33, Minories, E.C., has been dissolved by mutual consent as from December 30th, 1899. Mr. Leopard retires, and the business will be carried on in future at the same address and under the old style (Haines and Co.) by the remaining partner, Mr. John Batcheler.

Repairs to the Thames Embankment.—About a year ago a heavily-laden collier barge crashed into the stonework of the Thames Embankment opposite the Temple Station. The stones upon which the lamp-posts stand are of solid granite and weigh six and a half tons. It will be readily understood that it is no easy matter to get such a weight into a position almost overhanging the river, or to get the old stone out. The work is not likely to be completed for some time.

City and Guilds of London Institute.—The prizes and certificates gained by the students in connection with the City and Guilds of London Institute were presented on Thursday evening last by Sir Douglas Fox (President of the Institution of Civil Engineers). He said that to specialize in study too early was a great mistake. The great point was to lay the foundation as wide and as broad as possible. That done, the next thing was to properly apply what had been learnt.

The Municipal Year Book for 1900 has just reached us. The book is a valuable guide and reference book to municipal bodies, statistics, officials, and addresses. Additions have been made to every section and several new chapters introduced. The Irish section, describing the working of the new Government Act, will prove of special interest. The same general plan has been followed as in former issues—the English towns being divided into great towns, county boroughs, and other incorporated towns. The larger urban district councils are also dealt with. The great municipal industries—the supply of water, of gas and electricity, the management of tramways, the erection of artisans' dwellings and of municipal lodging-houses—are treated in separate sections. The publishers of the work are Messrs. Edward Lloyd, Limited, of 12, Salisbury Square, E.C., and the price is 2s. 6d.

New Companies.

Hampden English, Limited.

This company was registered on February 5th by Singleton and Co., 8, Staple Inn, Holborn, W.C., with a capital of £18,000 in £1 shares, to acquire the business carried on at Stowmarket and in London and Ireland by J. H. English, and to carry on the business of timber merchants, sawmill proprietors, timber growers, saw and file makers, &c. The first directors (to number not less than three nor more than seven) are M. V. English, G. W. Whiting, C. P. Beevor, A. E. Moeran and J. H. English. Qualification, 50 preference shares. Registered office: Creeving Road, Stowmarket, Suffolk.

Owen and Co., Limited.

This company was registered on February 6th by Jordan and Sons, Limited, 120, Chancery Lane, W.C., with a capital of £1,000 in £10 shares, to acquire the business carried on at Yorke Street, Burnley, as Owen and Co., Limited, and to carry on the business of plumbers, glaziers, &c. The first directors (to number not less than two nor more than seven) are Thomas Preston (chairman), Alex. Fyfe and H. Foden. Qualification, £50. Remuneration as fixed by the company. Registered office: 7, Yorke Street, Burnley, Lancashire.

John Sadler and Sons, Limited.

This company was registered on February 7th by Jordan and Sons, Limited, 120, Chancery Lane, W.C., with a capital of £10,000 in £5 shares, to acquire the business carried on by J. Sadler at the Shidas Lane Brickworks, Oldbury, Worcestershire, and to carry on the business of manufacturers of and dealers in red, brown, brindle, blue, glazed, ventilating, fire and other bricks, roof and floor tiles, copings, plinths, cornice copings, &c. The first directors (to number not less than three nor more than five) are J. Sadler (chairman), P. J. Sadler (managing director) and E. Pincher. Qualification, ten shares. Remuneration of J. Sadler, £150 per annum; of P. J. Sadler, £208 per annum, residence, and 5 per cent. of the net profits. Registered office: Shidas Lane Brickworks, Oldbury, Worcestershire.

Malkin Tile Works Company, Limited.

This company was registered on February 7th by Waterlow and Sons, Limited, London Wall, E.C., with a capital of £25,000 in £10 shares, to acquire the business carried on by E. Malkin and S. Malkin, at Newport Lane, Burslem, Staffordshire, under the style or firm of the Malkin Tile Works Company, and to carry on the business of china and earthenware manufacturers, and manufacturers of and dealers in pottery of any description. The first directors (to number not less than two nor more than three) are S. Malkin, H. Wood and J. Cope. Qualification, £50. Remuneration of S. Malkin, £832 per annum; others as fixed by the company.

Ford and Company, Limited.

This company was registered on February 8th by H. S. Bird, 50, Grey Street, Newcastle-on-Tyne, with a capital of £5,000 in £1 shares, to acquire the business carried on by C. B. Ford at Newgate Street, Newcastle-on-Tyne, as Ford and Co., and to carry on the business of drysalts, brush makers, oil, colour, and varnish manufacturers, importers and merchants, &c. The first directors (to number three) are C. B. Ford (managing director), G. R. Leah (chairman) and F. Bentley. Qualification, fifty shares. Remuneration of C. B. Ford, £250 per annum. Registered office: 60, Newgate Street, Newcastle-on-Tyne.

A UNIQUE OFFER is made this week to all collectors of twenty shillings and upwards for the **BUILDERS' JOURNAL Shilling Fund**. For particulars see page 35.

Professional Practice.

Belfast.—Donegall Square Church has been reopened after the completion of an extensive scheme of renovation. The re-painting of the interior and the re-polishing of the furniture, with the substitution of electric light for gas light, constitute the chief improvements. The walls are coloured green, which is relieved of any approach to sombreness by the imitation panel-work and mouldings being finished in cream and gold respectively. The organ has undergone some repairs, which contribute materially to its efficacy. The sanitation was carried out by Mr. Isaac Copeland; the electric lighting by Messrs. Smith and Parks, Mr. Greenhill acting as consulting electrical engineer; and the painting by Messrs. George Morrow and Sons, of Clifton Street, Belfast.

Bramford, Ipswich.—The Ecclesiastical Commissioners having had their attention called to the damp state of the chancel walls of Bramford Parish Church reported that the best things to do would be to render the lower parts in cement and to panel the walls with oak. The panelling and some new choir stalls have been designed by Mr. Caroe, of the firm of Messrs. Christian. The style of the stalls is late Gothic, each seat for the boys being separated by a small column, which gracefully runs up into the book-rest of the men's seat. Every seat, both for men and boys, has open carved work, each compartment being of a different design. The men's seats terminate at each end with a suitable clergy stall. There are seven seats for boys and five for men on each side. The panels which line the wall on each side, from the screen to the east wall of the chancel, are continuously separated into small sunk compartments by arrow heads, and at certain distances there is a carved member. The sedilia are also lined with similar panelling. The whole of the panelling is surmounted by carved capping, the wood used throughout being Austrian oak, which has been fumigated. The flooring of the chancel and sanctuary have been relaid with light grey and yellow tiling, and two handsome red Devonshire marble steps, of the quality called Brèche Sanguine, have been placed under the altar. The panelling and the tiling of the floor, the altar rails, and the screen have been given by the Ecclesiastical Commissioners. The stalls and the flooring of the sanctuary, and the altar steps are the gift of a friend of the church. The work of the renovation of the chancel is of a character worthy of the edifice, which has several features of special antiquarian interest. The screen, for instance, is dated about 1250, and it is stated that there are only five of this period to be found in the Kingdom. The nave is separated from the aisles by handsome massive pillars, and visitors to the church, which, by the way, is very conspicuous to travellers by the Great Eastern Railway, should not omit to inspect the font cover, which is Elizabethan (about 1550), and opens with wings on each side.

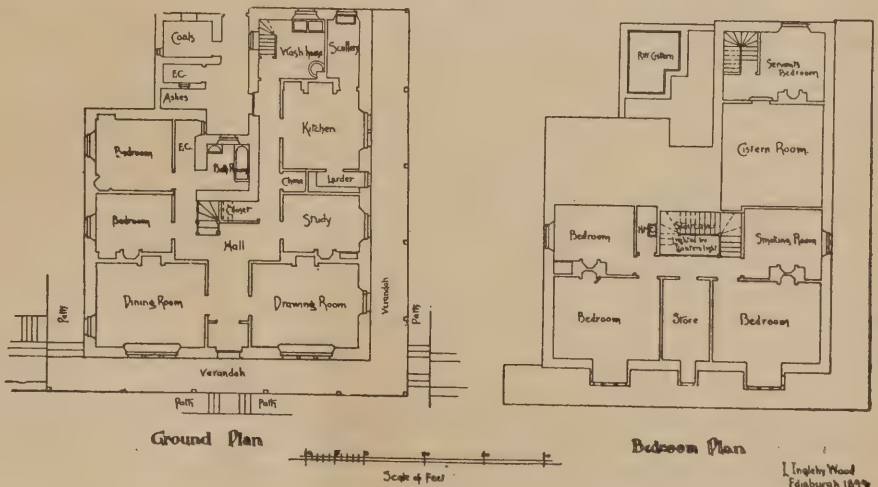

Bristol.—The new school for boys and girls erected by the Bristol School Board at Summerhill, St. George, was formally opened last week. The older Summerhill school, accommodating infants, faces the main road; the new building occupies a site adjacent to it and fronting Plummer's Hill Road. It has been designed for 350 boys and the same number of girls, and is of blue pennant, with freestone dressings. On the ground floor is a central hall, about 60ft. by 25ft., and round it are ranged seven classrooms and rooms for teachers. The apartments are well lighted and are provided with large windows through which the head teacher in the central hall can exercise a general oversight of the work. This floor has been allotted to the boys. The girls find accommodation on very similar lines on the floor above, the only difference being that the central hall is loftier, the roof being of open timber work. The floors are of fireproof construction—iron girders supporting concrete—and are laid with blocks arranged herring-bone

fashion. Mr. F. Bligh Bond, F.R.I.B.A., was the architect of the new building, and Mr. G. Humphreys the contractor. The school is warmed by hot-water appliances by Messrs. J. Crispin and Sons.

Dryburgh.—The house illustrated on this page is for Mr. W. Mitchell, of Edinburgh. The contractors are Messrs. R. and J. Greene, of Bowden, St. Boswells. The house itself is built of local red sandstone, rubble walls and red sandstone dressings, and the walls are to be rough cast and lime whitened. The roof covering is of Edwards' Ruabon tiles. A water supply was obtained after much trouble by boring an artesian well about 300ft. deep; the water is brought to the surface by means of compressed air. The building is on the slope of a hill and commands a magnificent view of Eildon Hills and the river Tweed.

mental and vocal music rooms, improvement of the residence house by the enlargement of the dining hall and the addition of several bedrooms. The increased size of the Jellicoe Hall demanded a more imposing approach than it formerly had, and the architect has endeavoured to make the entrance hall and staircase to the Jellicoe Hall a feature in his design. A system of exhaust ventilation, has been provided, and Messrs. Maguire and Gatchell are responsible for the heating of the college by the American radiator system. The building work has been carried out by Messrs. Samuel H. Bolton and Sons, from the design and under the superintendence of Mr. R. Caulfield Orpen. The cost has been about £71,000.

Durham.—The new gymnasium which has been erected in connection with the Durham

HOUSE AT DRYBURGH, N.B. L. INGLEBY WOOD, ARCHITECT.

It is situated about a mile and a quarter from St. Boswells railway station, and is close to the famous ruins of Dryburgh Abbey.

Dublin.—The building operations which have been in progress for the last twelve months at the Alexandra College are now practically complete. A portion of the college premises adjoining the Jellicoe Hall has been brought into harmony with the rest. It is intended, in the near future, to still further extend this treatment of the exterior, so as to mark clearly the limits of the college property. The additional accommodation gained by these alterations may be thus summarised:—Enlarged Jellicoe Hall and gymnasium under it, a spacious cloak room, a series of classrooms over the Hall, and over these again instru-

Grammar School is of coursed Dunhouse stone, with mullioned windows high in the walls, and is designed in the seventeenth century style. The building consists of a gymnasium, with a porter's lodge adjoining, and dressing rooms, with a shower bath for the use of the members. A staircase from the main porch leads to a gallery that extends along one side and one end of the building to accommodate the spectators at gymnastic displays. The gymnasium is 60ft. long by 30ft. wide by about 25ft. high, and is floored with wood blocks and panelled round with wood. It has been fitted up by Messrs. Stempel, of Regent's Park, London. The work has been carried out by Messrs. Gradon and Sons, of Durham. Mr. W. S. Hicks, of Newcastle-on-Tyne, was the architect.

Views and Reviews.

AUGUSTE RODIN.

The attention of all true lovers of art should be directed to whatever is shown in England of the works of "the greatest living sculptor of France. Having said this, and recommended a visit to Carfax and Co., Ryder Street, there remains but little to say, for other critics have been there, and found that the matter for anything but a very brief notice is wanting. The sketches and studies are easily seen to be those of an absolute master, and hardly less interesting than selections from the leavings of other great artists might be. Comparing Rodin's studies with those of past masters we find what they have in common to start with, but there are differences, fundamental and temperamental, which will force them apart some day, and far as the poles asunder we find their achievements to be. There is this to be said for Rodin—that he must be compared with the greatest or none, and as we find his name coupled with Michel Angelo's in some of the notices which have appeared, it seems that just this should be said on our side. His influence as a teacher has probably been greater among the sculptors of this generation than that of anyone else, but as a master he is idiosyncratic, standing alone to be left alone rather than slavishly copied.

It has been remarked very truly that modelling is not sculpture, and that a clay model does not necessarily become monumental by merely becoming perdurable, as when cast into moulds to re-appear as a bronze. There might be an interesting debate on this point, as it involves the whole question of style, and I should like to have other opinions.

E. R.

TWO FAMOUS CHURCHES.

We have so frequently had occasion to call attention to the usefulness and general attractiveness of the volumes in the series of handbooks known as "Bell's Cathedral Series," that the publication of a new volume does not call for any extended notice. It is sufficient to remark that the excellencies which characterise the series as a whole are fully represented in this latest volume. The illustrations are from photographs by the author, Rev. Thomas Perkins, M.A., Rector of Tarnworth, Dorset, and are sufficiently numerous and sufficiently architectural in character to render the volume interesting and instructive to the architectural student. Wimborne Minster has suffered much at the hands of the nineteenth century restorer, and we are glad to note that Mr. Perkins apprises this misplaced energy at its right value. Both Wimborne and Christchurch are full of historic as well as architectural interest, and the volume, which is the result of Mr. Perkins's studies and observations, is an eminently readable one.

"Wimborne Minster and Christchurch Priory" (Bell's Cathedral Series); by Rev. Thomas Perkins, M.A., F.E.A.S. London: George Bell and Sons. 1s. 6d.

RECORD OF THE TIMBER TRADE.

The annual issue for 1900 of "Timber and Wood-Working Machinery" is a most interesting one, and fully equal to the previous ones. As a review of the timber trade in its various branches this annual is unsurpassed, both for wealth of illustrations and entertaining and useful letterpress. The subjects treated of this year are the mahogany industry of British Honduras, the timbers of Tasmania, the greenheart industry of Demerara, New Zealand and its timbers, the manufacture of timber on the Pacific Coast of North America, the export timber trade of Western Australia, the teak trade of Siam, the sawmills and timber yards of High Wycombe; miscellaneous notices are given of well-known firms in the timber trade and novelties in wood-working machinery. A plate containing portraits of the leading sawmill engineers of Europe is given as a special supplement, with notes on their careers.

"Timber and Wood-Working Machinery: Special Illustrated Issue, February, 1900." Edited by W. L. Bird. 1s. London: The Botolph Press, Ltd., Swedland Court, Bishopsgate, E.C.

New Patents.

These patents are open to opposition until March 24th.

1899.—Moving Stairways.—1,618. J. BUCHANAN and G. F. THOMPSON; both of Liverpool. This stairway consists of a series of flaps or treads hinged at the back to two endless chains that pass around wheels at the top and bottom of the staircase. The treads are kept horizontal by means of trunnions travelling in grooves on the inner faces of the stringers, and are composed of a number of narrow strips connected together by a backing of flexible material. Moving sides, consisting of wide endless bands running over vertical drums, are provided, and at the top end the treads fold down on the chain to pass under the tapered edge of the landing.

Sewer or Drain Covers.—1,735. H. LINDLEY, Liverpool. The cover has two doors pivoted and counterbalanced. Normally they lie in the shape of the letter V against a kind of grid, which is the prolongation of two deflectors. Near the bottom of the casing, on the inside, is a shelf for receiving disinfectant. The doors are fitted with rubber to improve the joint. It is claimed that the device effectually prevents the escape of smells and gases.

Door and other Knobs.—2,802. G. H. BLACKHURST, Birmingham. To avoid having cast-brass neck parts which require to be tapped, a metallic wire coiled to form a screw is used. It is leaded into the neck, which is then practically solid, having a screw of a durable character.

Syphon Flushing Cisterns.—3,916. S. CLARK, Glasgow. At the end of the short leg of the syphon there is a chamber containing a rubber ball or bladder, from which a pipe depends to the closet, ending in a ball. When this latter is squeezed the bladder is expanded, displaces the water in the short leg, and so starts the syphon.

Portland Cement Manufacture.—4,813. L. WHITE, London. The fuel is mixed or ground with the slurry (or other material from which cement is to be made) and fed into a rotary furnace; it is preferable to use 25 per cent. or 30 per cent. of fuel. By this arrangement it is claimed that there is great economy of fuel and labour, and a larger output of cement.

Water Closets.—7,836. J. A. REID, Glasgow. The essential part of this invention consists in having a sealed cistern and a valve for starting the flush at the foot of the pipe falling from the cistern. No syphon is used. When the valve is opened (it is controlled by a handle) the water in the fall pipe and cistern is discharged, and at the same time a cock on the service pipe is closed; this cock opens when the lower valve closes.

Sewage Purification.—20,759. T. J. BARNARD, Truro. The solid is separated from the liquid matter by passing the sewage through a series of beds; the first consists of coal slack of about the size of walnuts; the next of fine coke or coke breeze; and the last of broken charcoal. After passing through these beds the liquid undergoes upward filtration through lime. The sludge is mixed with coal tar and used as fuel; 2½ per cent. of tar is added for open-grate purposes, and 10 per cent. for steam producing purposes.

Pulley Blocks.—22,852. E. ALLDAY and W. T. EADES; both of Birmingham. The sheave is made in the form of a ring and runs against rollers on its inner periphery. It also has a projection or rib fitting into grooves in the rollers.

Door Springs.—23,590. J. and T. KELLY, Edinburgh. Inside a casing secured to the floor are two built-up springs connected to two levers. To the end of each of these levers is attached a chain connected with a cam on the door spindle. The door will thus close from either side.

The following specifications were published on Saturday last, and are open to opposition until March 31st. A summary of the more important

of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—1,387, BRYDEN, window blinds. 1,466, MOORE, taps. 2,327, PEASE, structural arrangements applicable to roofing and walling. 2,373, DUCAT, supplying air to filters for the purification of sewage. 2,779, ROUNSIVELL, travelling crane or hoist. 4,086, PEAKE, method of and apparatus for feeding "tile-bats" to tile presses. 4,241, PURVIS, method of manufacturing tiles, pipes, chimney pots and bricks. 4,628, MILLS (*Pagnon*), process for the production on glass of decorative pictures or designs. 4,814, WHITE, manufacture of Portland cement. 5,051, TAILBY, guards for circular saws. 5,188, DOULTON, closet supply-valve fittings. 5,293, PEAKE, method of and means for treating sewage and trade effluents. 5,305, ERQUEM, stencil or similar copying apparatus. 5,452, DAVIDSON, centrifugal fans or pumps. 5,516, GREEN, paper hangings. 5,755, LAUERMANN and GAZE, manufacturing stucco or plaster-like articles, ornaments, or surfaces. 6,029, BEAN and RINGWOOD, apparatus for generating acetylene. 6,277, MOSS, method of and means for attaching handles to the heads of brushes and mallets. 6,988, MORRIS, pipe fittings for use in connection with heating apparatus. 10,699, JONES, street lamp posts, electric light standards, &c. 14,369, GILSON and BOOER, leaded lights for stained glass. 16,843, TATTERSALL, tap filter and splash preventor. 20,780, DOCKREE, brushes. 23,399, LANGENSIEPEN and BACHMANN, process of manufacturing granular, grinding, cutting, and sawing material. 23,503, WELTY and RUMBAUGH, machine for grinding and polishing plate glass. 23,689, NEFKENS, appliances for drying roofing tiles, bricks, &c. 25,026, ALEXANDER, mechanism for feeding material to a brick-making machine. 25,518, VAISSE, valves or cocks. 25,646, RAMSEY, DAVIES and LEE, top for chimneys, ventilators, &c.

COMING EVENTS.

Wednesday, February 21.

SOCIETY OF ARTS.—Mr. Edwin Bale on "Artistic Copyright." 8 p.m.

SURVEYORS' INSTITUTION.—Annual Dinner at Holborn Restaurant. 6.30 p.m.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Mr. Henry R. Kenwood, M.B., D.P.H., F.C.S., on "Methods of Disinfection." 8 p.m.

PROVIDENT INSTITUTION OF BUILDERS' FOREMEN AND CLERKS OF WORKS.—Ordinary Meeting at 8 p.m.

BRITISH ARCHAEOLOGICAL ASSOCIATION.—Meeting at 8 p.m.

Thursday, February 22.

CARPENTERS' HALL.—Prof. T. Roger Smith, F.R.I.B.A., on "English Halls and Mansions." 8 p.m.

INSTITUTION OF MECHANICAL ENGINEERS.—Meeting at 8 p.m.

SOCIETY OF ARCHITECTS.—Mr. E. J. Naldrett on "The Legal Position of Architects in Relation to Local Authorities." 8 p.m.

INSTITUTION OF ELECTRICAL ENGINEERS.—Mr. Ernest Sammelson on "Improvements in the Longworth Power-Hammer;" and Mr. Ewart C. Amos on "Portable Pneumatic Tools." 8 p.m.

YORK ARCHITECTURAL SOCIETY.—Mr. A. J. Penton on "Building Traditions."

ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Arthur Thomson, M.A., M.B., on "The Anatomy of the Human Form: The Lower Limb." 6.15 p.m.

SOCIETY OF ANTIQUARIES OF LONDON.—Meeting at 8.30 p.m.

Friday, February 23.

ARCHITECTURAL ASSOCIATION.—Mr. A. W. Henning on "The Exterior Treatment of Sharp or Acute Angles in Street Buildings." 7.30 p.m.

THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE ARCHITECTURAL CRAFTSMEN'S SOCIETY.—Mr. James Lochhead, A.R.I.B.A., on "The Decay of Building Materials." 8 p.m.

BIRMINGHAM ARCHITECTURAL ASSOCIATION.—Mr. Edgar Wood, A.R.I.B.A., on "An Architect's Experience in the Development of Design." 6.45 p.m.

ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Lewis F. Day on "Ornamental Design."—VIII 11.30 a.m.

SANITARY INSTITUTE.—(Lectures and Demonstration for Sanitary Officers: Part II.)—Paper on "Calculations, Measurements, and Plans and Sections." 8 p.m.

INSTITUTION OF CIVIL ENGINEERS. (Students' Meeting.)—Mr. B. Humphrey and Mr. H. E. O'Brien, B.Sc., on "Bearing Springs." 8 p.m.

Saturday, February 24.

DUNDEE INSTITUTE OF ARCHITECTURE.—Mr. Charles Ower on "Travel, Part of an Architect's Education." 7 p.m.

EDINBURGH ARCHITECTURAL ASSOCIATION.—Visit to Shrubhill Cable Station and Macdonald Road Electric Light Station.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Inspection and Demonstration at the Sutton Sewage Works, at 3 p.m., conducted by Mr. C. Chambers Smith.

ARCHITECTURAL ASSOCIATION.—Second Spring visit.

PEOPLE'S PALACE ARCHITECTURAL SOCIETY.—Visit to the London County Council Sewerage Works at Barking.

Monday, February 26.

SURVEYORS' INSTITUTION.—Ordinary General Meeting at 8 p.m.

VICTORIA AND ALBERT MUSEUM (South Kensington).—Mr. Hugh Stannus, F.R.I.B.A., on "The Historic Evolution of Applied Art: XVI.—Renaissance Christian Art." 6 p.m.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Mr. Joseph Priestley, B.A., M.D., M.R.C.S., D.P.H., on "Ventilation, Warming and Lighting." 8 p.m.

PHILOSOPHICAL SOCIETY OF GLASGOW (Architectural Section).—Mr. George Walton on "Personal Experiences in Decorative Work." 8 p.m.

Tuesday, February 27.

ROYAL SOCIETY OF ANTIQUARIES OF IRELAND.—Meeting at 4 p.m.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Inspection and Demonstration at John Knight and Sons' Soap Works, Silvertown, at 8 p.m.

Wednesday, February 28.

SOCIETY OF ARTS.—Professor Carus-Wilson on "Pneumatic Despatch." 8 p.m.

SANITARY INSTITUTE (Lectures and Demonstrations for Sanitary Officers).—Mr. J. C. Thresh, D.Sc., M.D., on "Water Supply, Drinking Water, Pollution of Water." 8 p.m.

EDINBURGH ARCHITECTURAL SOCIETY.—Mr. John Begg on "Johannesburg Before and After the War, from an Architect's Point of View." 8 p.m.

Thomas and Edge	£3,512	J. Jarvis	£2,431
Strange and Sons	2,638	Battley, Sons, and	
R. L. Tonge	2,500	Holness, London*	2,249

* Accepted.

CONTRACTS OPEN.

TO CONTRACTORS AND OTHERS.

The Ilford Urban District Council hereby give notice that they are prepared to receive TENDERS for the ERECTION of

1. A Pavilion.
2. A Bandstand (Iron).
3. Two Lodges.
4. Iron Fencing.

The Pavilion comprises a large refreshment room, kitchen stores, balcony, and lavatories for both sexes. The Bandstand to be 24ft. in diameter, to be erected on a brick foundation provided by the Council.

The Lodges will contain three bedrooms, parlour, kitchen and scullery.

The Iron Fencing, unclimbable, will be about 160yds. in length and 5ft. high.

Plans and specifications can be seen, and forms of Tender obtained on application to the Surveyor to the Council, Mr. HEBBERT SHAW, A.M.I.C.E., at his Offices 7, Cranbrook-road, and bills of quantities obtained upon a deposit of £5 being paid, to be returned on receipt of a bona-fide Tender.

Sealed Tenders, addressed to the Chairman, and endorsed "Tender for —" (as the case may be), must be sent to me here on or before MONDAY, MARCH 12th.

The Council do not bind themselves to accept the lowest or any Tender.

Council Offices, Ilford, Essex,
JOHN W. BENTON, Clerk to the Council.
February, 1900.

BUILDERS' LIFTING APPLIANCES.*

By DAVID SKINNER.

(Concluded from page xii of the supplement to No. CCXLII.)

Shoring and Under-Pinning.

FOR this kind of work a screw arrangement can be used. The value of a screw, so far as its mechanical power and the amount of motion obtained is concerned, depends on its pitch only, while the strength depends upon the area of the transverse or cross section, the amount of both of which can readily be determined. As will be seen on reference to Fig. 16, the screw jack (sometimes called a bottle jack) consists of a hollow cylindrical casting A, with an internal square screw thread cut in the upper part; a screw B, provided with a similar thread, passes into it, the screw having a spherical head through which two holes are made at right angles to each other for the insertion of a lever C, at the end of which P is applied.

To avoid the extreme friction that would occur if the part which was in contact with the weight revolved with the screw, it is fitted loose upon it, being riveted in position, as shown at D; this portion is serrated. To determine the mechanical advantage, let P denote

FIG. 16

the power applied at end of lever, l length of lever, p pitch of screw thread, and W weight to be supported. Then the motion of W for one revolution of screw $= p$; work of W per revolution $= Wp$; motion of P per revolution $= 2\pi l$; work of P per revolution $= P \times 2\pi l$; and these are equal $\therefore P \times 2\pi l = Wp$; or $\frac{P}{W} = \frac{p}{2\pi l}$.

$P : W :: p : 2\pi l$. The proportion between P and W can be obtained by considering the inclined plane by the hypotenuse of which the helical curve of the thread is formed on the cylinder of the screw. The principle of the inclined plane is that the weight, plus the height of the plane, equals the power multiplied by its base. The base as applied to this case is considered to be the circumference of a circle which the end of the lever describes. This gives the same formula as before. Example: $P = 20$ lbs.; distance from centre of screw to point at which P is applied, 24 in.; pitch, 1 in. Find weight supported. P 's motion through one revolution of screw $= (2 \times 24 \times \pi)$ in.; work of $P = 20 \times 2 \times 24 \times \pi$; W 's motion lin. \therefore work of $W = W \times 1$. These are equal, or $W \times 1 = 20 \times 2 \times 24 \times \pi$ $\therefore W = 3,015.936$ lbs., or about 1 ton 7 cwt.

To determine the load that can safely be put on a screw jack so that the threads of the screw will not give way by shearing, we must take the area resisting the shearing stress and multiply it by a safe shearing stress per square inch, and the result will be the safe load. In this case the pitch of the screw is 1 in., which gives thickness of thread $\frac{1}{2}$ in. There is also

FIG. 17

four times the pitch in the nut or upper part of the casting. Therefore the area $=$ circumference of cylinder $\times 4 \times \frac{1}{2}$ in. $= 2$, which gives number of square inches. Assuming a screw of 3 in. diameter, then 3 in. $\times 3.1416 \times 2 \times 1 = 18.8496$ sq. in. Cast-iron has a safe shearing stress of $2\frac{1}{2}$ tons per square inch; then $18.8496 \times 2\frac{1}{2} = 47.124$ tons $=$ safe load on top of screw. This result shows that the shearing of the screw jack is rather a remote contingency, as it would take over 700 lbs. applied to the lever to lift 47 tons.

A worm and worm wheel may be used in combination with a screw, as in a common form of screw jack. This arrangement of lifting jack is one not very often met with in ordinary building work, but, as it has a very high mechanical advantage and is not too intricate in its mechanism, it may be considered at this point. Referring to Fig. 17, P is applied to a lever handle A fitting on the end of a shaft to which the worm B is keyed. The worm gears with a worm wheel C , which revolves in an opening made in the hardwood portion F , of which the jack is formed; the pressure acts on an iron plate. The worm wheel has a thread cut on its inside, forming the nut for the screw D , which screw cannot revolve as it moves in a groove cut in the body F . The lower part of the screw has a projecting piece G which is useful for raising heavy articles when they are near the ground. Iron plates H and K are secured to the sides of the jack, forming bearings for the worm shaft, as shown.

The motion is transmitted from the handle to the worm and worm wheel, and the screw rises or falls according to the direction of rotation of the handle. This type of jack is also made with the part F of cast-iron, though similar to the one illustrated in other respects. To determine the proportion between P and W , we have to consider their relative motions, and, as the work of each is the same, $P : W :: W$'s motion : P 's motion. In one revolution of the worm wheel the weight is raised a distance equal to the pitch, but to produce this one revolution the worm must in this case revolve $\frac{n}{3}$ times, as three teeth of

the worm wheel have been moved through in one revolution of the worm. Or, if we denote length of handle by l , number of teeth in worm wheel by n , number of threads in worm by N , and pitch of screw by p ; then $P \times \frac{2\pi l n}{N} = Wp$, or $P : W :: pN : 2\pi l n$.

$\therefore P = \frac{W p N}{2\pi l n}$, $W = \frac{P 2\pi l n}{p N}$ and $\frac{W}{P} = \frac{2\pi l n}{p N} =$ mechanical advantage.

Example: A worm wheel having 16 teeth forms the nut of a screw, 1 in. pitch; an endless screw with three threads driven by a lever 16 in. long gears with the wheel. Find the pressure exerted by the end of the screw when 20 lbs. is applied to the lever. $W = \frac{2\pi l n}{p N} = \frac{20 \times 16 \times 2 \times \pi \times 16}{1 \times 3} = 10,723.984$ lbs., or about 4 tons 16 cwt. If the worm or endless screw were single threaded, the answer would have been three times as great; if double threaded it would have been one and a half times as great. The disadvantage of this jack is that sometimes at the

critical moment the handle will not turn, perhaps on account of there being a great pressure acting between the worm wheel and the iron plate, consequently requiring a large amount of friction to be overcome when the worm wheel revolves.

An exceedingly useful lifting jack is the hydraulic jack. A section of such a jack is shown at Fig. 18. A hollow cylinder D fits on the ram B , the joint between the two being made watertight, by suitable means; leather packing rings are most suitable. C is a store for water, A is the delivery valve or clack, and B is the suction valve. These valves are kept in position by spiral springs; the valves themselves may be made of brass or copper, preferably of copper, though brass would, of course, be cheaper. K is the plunger, which passes into the pump barrel by a water-tight joint, L is the handle by which the plunger is operated, and H is a cock for relieving the pressure.

FIG. 18

When the plunger is lifted the water in store is forced through the suction valve B into the pump barrel. In the down stroke of the plunger the water in the barrel is forced through the delivery valve A into the hollow cylinder. The base of the ram resting on the ground, the increase of water on top of the ram forces up the upper part of the jack, and thus increases its length. The principle of the hydraulic lifting jack is that a pressure acting per unit of area on the plunger produces an equal pressure per unit of area on the ram, the change of pressure, therefore, being in the proportion of the respective areas. In such an appliance the mechanical advantage of the lever or handle is 12 to 1 , the diameter of the lifting ram is 3 in., and the diameter of the plunger is $\frac{1}{2}$ in. What weight can be lifted theoretically when a pressure of 20 lbs. is applied to the end of the lever? Let P denote power applied at end of lever handle, l the leverage, D^2 the area of ram, and d^2 the area of plunger. Then $P : W :: d^2 : D^2 \times l$; or $W = \frac{Pl \times D^2}{d^2}$, $P = \frac{W \times d^2}{l \times D^2}$. $\therefore W = \frac{Pl \times D^2}{d^2}$

$\frac{20 \times 12 \times 3 \times 3}{\frac{1}{4} \times \frac{1}{4}} = 2821.2$ lbs., or 1 ton 50 cwt.

21 lbs.

Working and Fixing Lifting Appliances.

If a derrick pole is employed for the raising of a heavy load, it should be guyed from four points fixed to the ground, or to anything suitable in or around the building. The reason why four guy ropes should be used is that it is much safer than using three, the fewest that can be used, and also that the pole can be more readily drifted in the direction required for placing the piece of work in

* A paper read before the Glasgow and West of Scotland Technical College Architectural Craftsmen's Society on January 26th, 1900.

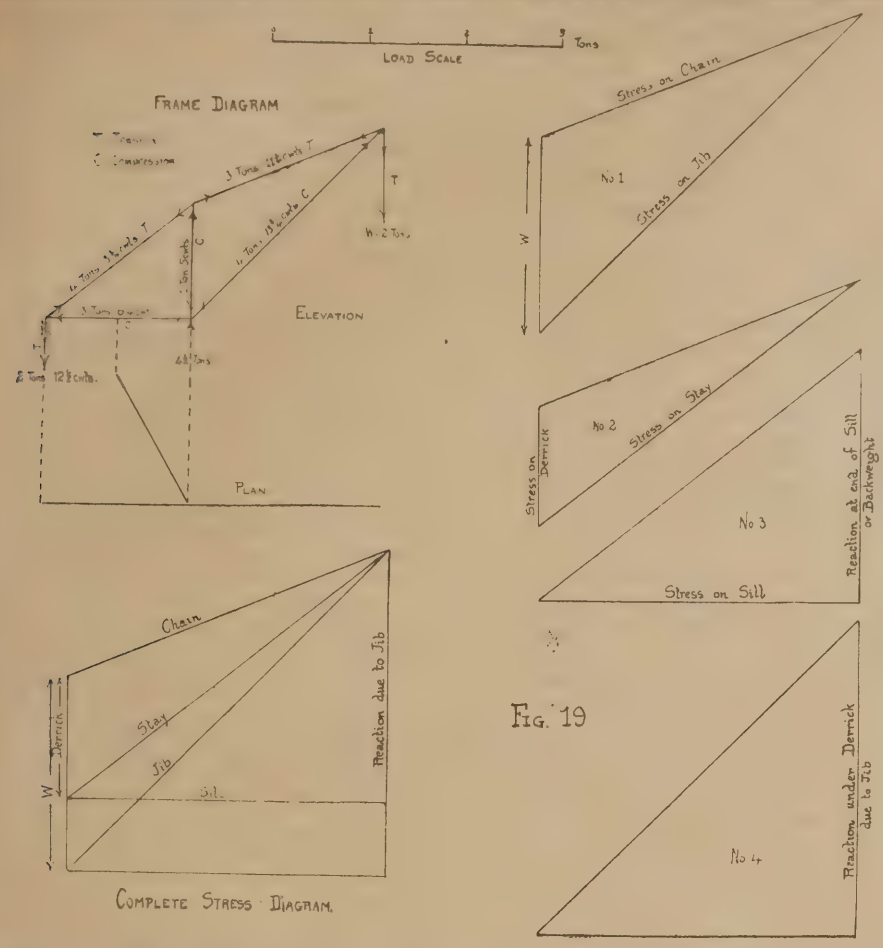

Fig. 19

arriving graphically at the components of the forces acting at the angle between the plane of the jib and the stay.

First case (Fig. 19). Suppose that we take one triangle at a time. We commence with setting down to a convenient scale the amount of the load, and, parallel to its direction, from the lower end of the line, another line is drawn parallel to the jib to meet a line drawn from the other end of line and parallel to the chain holding up the jib. These two lines measured to the same scale will give the amount of stress in the jib and chain respectively. To continue the process, set out the line of the chain, equal in length to that already found and parallel to its direction, and from one end of the line draw a line parallel to the stay to meet a line parallel to the derrick drawn from the other end of the line. These two stresses are determined as before by measuring the lines to the same scale. This brings us now to the point at which the amount of reaction or back weight can be determined. A line is set out equal in length to the stay stress, and parallel to it from the lower end a line is drawn parallel to the sill to meet a line drawn parallel to the reaction, which is vertical. This vertical line is now measured and gives the reaction, while the horizontal line gives the stress in the sill. The reaction under the derrick remains to be determined. The stress in the jib is already known. Set out the line equal to that stress and parallel to it, and from the lower end of the line draw a line parallel to the sill to meet a line drawn parallel to the reaction, which is also vertical. This vertical line gives the reaction due to the jib. To this must be added the stress down the derrick caused by the chain and stay. It will be seen that the sill stress measured in these last two triangles is the same, which, of course, ought to be the case if the frame is to be in equilibrium.

The same procedure is carried out in the second case until we come to resolve the amount of stress in the imaginary or auxiliary stay and sill into components of the original forces. Given the same frame diagram as before, but with the jib in line with auxiliary stay, to find the stresses in the different members. (See Fig. 20.)

The two cases shown give the stay in tension and the sill in compression; and also the amount of back weight required; but if the jib were swung round till it almost touched one of the stays, then that stay would be in compression and the sill would be in tension.

position. The guy ropes should be of such length that they may have a good purchase over the pole; if fixed to the ground, the point of fixing from the foot of the pole should not be less than twice its height. A double-purchase crab is the most suitable arrangement for working in conjunction with a derrick pole. The rope from the crab should be led to a single-pulley block fixed to the bottom of the pole, then up to a block hung from the top, usually an iron bolt driven through the pole, and long enough for a rope or chain sling to hang over both ends. To this sling the top block is hung. If the load is very heavy, pulley blocks may be used, as the stress on the rope is thus reduced. The pole need not be let into the ground, as the pressure acting downwards on the pole is the weight plus the power, and it is only the power which acts horizontally that tends to pull the pole towards the crab; merely resting the pole on the ground is, therefore, sufficient.

Shear legs may also be used for the same purpose, and are only guyed from two points, the load hanging down between the two legs. The rope in this case goes right to the top, and the crab should be placed as near as possible to the shear legs. Pulley blocks hung from a beam exert a pressure on that beam of the power plus the weight, in addition, of course, to their own weight.

In the ordinary crane that is used in building work, the proper securing of the structure is the important part of the erection. The fixing of the stays to the sill and the amount of back weight to be placed at that point is each of the utmost importance, as the weight prevents the crane from overturning. The stress in each member of the structure can be determined graphically by triangle of forces, namely, that if three forces acting on a point are in equilibrium, and a triangle is drawn having its sides respectively parallel to the forces taken in order, then the forces will be proportional to the sides of the triangle. We must have a known force to start with, and it is usually the load hanging from the extreme end of the jib which is taken. It will be readily understood that the swinging round of the jib will cause a varying stress to come on each part of the structure, though the stress on the jib will not vary. But if the jib

is raised or lowered the stress on it will vary, as will also the stresses on the other members of the framework. It will be sufficient for our purpose to assume the jib to be standing in the same plane as one of the stays, and, for a second case, the plane of the jib to bisect the angle between the two stays. In the first case we may take it that the other stay is doing no work, or at least a very small amount, and therefore it need not be taken into account. In the second case it is a good principle to assume an imaginary stay and sill to be in the same plane as the jib, and so

Fig. 20

This would be the weakest position for the jib to be in, as there is only the weight of the crane keeping it down at the bottom of the jib plus the resultant of the stress on the jib. The load hung on the point of a jib should be considered a live load, not a steady dead load, or, if considered a dead load, a factor of safety of not less than eight should be used. Live loads are taken at double the dead load.

In lifting a load with any of the fore-mentioned lifting jacks the surface upon which the base rests should be perfectly flat and at right angles to the direction of the thrust, and at the same time the part resting on the top of the jack should be at right angles. If a large roof were to be raised a few feet or, say, a wooden house transferred from one place to another, or anything of that nature, screw jacks should be used. The number of these should not be spared, as the greater the number of points supported the less chance will there be of racking the framework. I say the screw jack advisedly, as it is the simplest and least liable to go wrong; it is quite strong enough and its price is less than that of any of the other appliances.

Greater care should be exercised in storing lifting appliances when not in use. How often do we see some of these thrown away in some corner exposed to all weather, getting red with rust? If there are any ropes in connection with them, these will soon rot and will be very untrustworthy and dangerous if not looked after. Rope pulley-blocks should not be left in position for any length of time. If they cannot be taken down after each day's work and put in a dry place, they should be covered by some material that will prevent water getting into them. Being alternately wet and dry will soon injure any rope. In drying also ropes twist in an aggravating way and cause an extreme friction in the working of the tackle. Screws and all parts of shafts turning in bearings should be covered with tallow.

There are numerous other machines used for lifting purposes in buildings, all more or less interesting, but in this paper I did not intend to particularise any machines, but rather to show in a general way the principles of their mechanism and to give such data as would enable anyone to apply it to any appliance he may come across and so determine the advantage to be gained by such appliance. In conclusion, it may be stated that steel wire is the best material to use for crane hoisting, as it is now made to stand a high stress; besides, it is well known that small wire can be made more uniform and strong in proportion than material of larger section. Hoists added to in height as the building proceeds have been advocated in preference to cranes placed high on gabbart scaffolds, on the score of greater safety to the public if the building should be on a busy thoroughfare; but hoists require small hand cranes on the top to place the materials, if heavy, in position, and, moreover, a hoist would not be suitable for lifting long materials, such as joists, beams, roof timbers, or steel girders. The danger of anything falling in the case of the hoist is confined to the area of the well, which is, of necessity, inside or on the face of the building. Sufficient has been said in this paper to show that a crane, crab or jack are simple enough machines, and there is no reason why any craftsman should not be familiar with any of them, and, if need be, take them to pieces, clean and repair, and fit them up again properly, saving time and expense.

The Dundee Plasterers, it is reported intend asking their employers for an increase in wages of 1d. per hour.

The Oldham Carpenters and Joiners have given a three months' notice to the employers for an advance of ½d. per hour on their present wage of 9d.

High Death Rate in Dublin.—The committee appointed by the Local Government Board to enquire into the causes of the high death-rate in Dublin (it was 43.8 per 1,000 persons living for the seven weeks ended February 3rd last) is now sitting.

Surveying and Sanitary Notes.

Bradford Sewage Experiments.—The shale filter-beds at the Brierly Sewage Works are to be extended at an estimated cost of £700.

Mason's Arms Court, Queen Street, Cardiff, has been declared by the medical officer of health to be unfit for human habitation. Proceedings are to be taken against the owners of the houses.

Street Improvements at Gateshead.—Alterations are now in progress that will give a clear way for traffic coming and going by West Street, while the turn into Mulgrave Terrace will be easier and safer. The wall at the bottom of High West Street is to be removed and carried 20ft. further back, doing away with six coal depôts. Wellington Street will then be brought into line with West Street.

Institute of Sanitary Engineers.—At a meeting of the Election Committee held on February 14th the following gentlemen were elected:—As Members: P. Baldwin (Wakefield), W. J. Cornwell (Betchworth), T. Fitchern (Claremont, S.A.), H. G. Nicholson-Lailey (Caerphilly, Glam.) and A. C. Remnant (Catford). As Associates: W. J. Collins (Harrow-on-the-Hill), E. W. Norman (Forest Gate) and P. J. Roddie (Waterford).

Improvements at Scarborough.—At a special meeting of the Scarborough Town Council last week it was resolved to promote a Bill in the next Session of Parliament to make an approach road to the new marine drive, and to alter the line of sea wall of the drive. It was originally proposed to establish electric trams along the sea front from the Aquarium to Peasholm, but owing to the strong opposition of the cab and carriage interests this has been waived.

Paris Dust Carts.—Paris is amusing itself with a little municipal squabble between the Council and chiffoniers. The Council is desirous of introducing new patent closed dustbins, to be emptied each morning into patent dustcarts. The chiffoniers seeing their trade about to disappear threaten to break up these new-fangled appliances. The feeling of the populace is said to be on the side of the chiffoniers. They do not wish to lose any opportunity of making a dust.

Refuse Destructor to be built at Southport.—At their last meeting, the Southport Town Council decided to accept the tender of Messrs. Horsfall and Co. to build a refuse destructor for the sum of £9,960 (exclusive of the chimney), and to instruct Messrs. Scott and Co. to prepare and submit designs and estimates for a chimney 150ft. high and of 5ft. internal diameter. The total cost will be about £13,000, and the destructor will comprise six cells, back to back, each cell capable of consuming about ten tons of refuse per twenty-four hours.

Pavement Cleansing.—By section 29 of the Public Health (London) Act, 1891, the duty of cleansing footpaths, as well as roadways, was imposed upon local sanitary authorities. Prior to this, occupiers and owners of premises were required to clear and clean their respective frontages. Experience during snowy and frosty weather since the change in the law has shown that, whereas the individual obligation was generally prompted fulfilled, the duty which now devolves upon public authorities is very often neglected, and as a result snow and ice remain on the footways as well as roadways for a dangerously long time, awaiting removal. Hence Mr. J. Lewis, the largest individual ratepayer in Marylebone and a member of the local Vestry, proposes that the latter should urge the Local Government Board to seek the repeal of the section named, and reimpose the work of cleansing the causeways on occupiers and owners. Further, he proposes that Vestries and District Boards of Works should be invited to support this representation to the Local Government Board.

Builders' Notes.

The Clerks of Works' Association of Great Britain recently held its seventeenth annual dinner at the Holborn Restaurant, when Mr. G. H. Fellowes Prynne, F.R.I.B.A., presided. The Association has now 170 members.

Liverpool Workmen's Dwellings Contract.—The Liverpool City Council has approved the acceptance of the tender of Messrs. Holme and Green, of Liverpool, amounting to £8,067 15s. 3d., for the erection of the second portion of labourers' dwellings in Dryden Street and Rachel Street.

Fined for Building without having Deposited Plans.—At the Knaresborough Petty Sessions on February 14th, John Brook, builder, of Bilton, Harrogate, was summoned by the Knaresborough Rural District Council for committing a breach of the building by-laws by erecting a house without his plans having been approved by the Council. The defendant was fined £3 and costs.

Large Building Enterprise in Leeds.—The report of the City of Leeds Central Estates, Limited, states that most of the old buildings have been demolished, and the new street leading from Duncan Street to Kirkgate partly formed. Plans dealing with the whole of the property have been prepared, and the contracts for the new buildings, which involve an expenditure, apart from the site, of nearly £100,000, have been let to Messrs. Armitage and Hodgson, of Leeds. Mr. T. W. Cutler, F.R.I.B.A., F.S.I., of London, is the architect. The greater portion of the scheme, which comprises a new Bull and Mouth Hotel, a large emporium facing Briggate, and twenty-two shops in Kirkgate, New Central Street, and Central Road, will be completed during the next twelve months.

Claim by a Clerk of Works.—Before Mr. Justice Bruce at the Gloucester Assizes last week an action was brought by John Gaven, clerk of works, against the Gloucester Corporation for £182, balance of wages. It was contended that plaintiff accepted the situation under the impression that he was to be paid for the job, which was estimated to last from sixteen to eighteen months. Defendants pleaded that plaintiff was engaged at three guineas a week, without any stipulated time, and could be dismissed at a week's notice, since he was paid weekly. Plaintiff claimed that three or six months was reasonable notice. His Lordship in summing up said that unfortunately there was no special usage in this trade. The jury found that plaintiff was entitled to six months' notice, and fixed the compensation at £81 18s., this being six months' salary, and grounded their verdict on the opinion that plaintiff could not get other employment during that time.

Frost and Household Water Supply.—Strictly speaking the safest course to pursue for the householder who suspects any disarrangement of his hot-water supply is to draw the fire and call in an expert to examine the fittings and determine what steps should be taken. With the high-pressure system, when frost momentarily interferes with the supply, there is no necessity to draw the fire, but this can be kept going quietly all night. In the case of the old or low-pressure system of supply the conditions are different, and the sudden rush of cold water into an empty, red-hot cistern must almost inevitably lead to an explosion. In this case, when a break in the water service has been detected, the only safe course to pursue is to draw the fire and call in a qualified plumber to remedy the defect. With regard to the ordinary cold-water supply, all consumers are advised to take measures to protect their service pipes in exposed positions by covering them with some non-conducting material, such as felt, bands of hay or straw, or wood casing filled with sawdust.

An Unconscientious Builder.—In the Queen's Bench Division of the High Court of Justice on February 10th the case of *Ward*

and Co. v. Wallis was heard. The plaintiffs are cement specialists carrying on business at 15, Great George Street, Westminster, and the defendant is a builder of Balham, S.W. The action was brought to recover £75 for work and labour done and materials supplied, and, alternatively, as money received by the defendant to the use of the plaintiffs. The facts were as follows: In January, 1898, the defendant entered into a contract with a Miss Barry for the erection of a mission hall at Bethnal Green for £2,277. The contract provided that certain patent concrete pavings in the building were to be supplied by the plaintiffs for £126 5s., and this sum was included in the bill of quantities upon which the defendant tendered. The plaintiffs did their work and obtained a certificate from the architect that £125 5s. was due to them, the amount having by agreement been reduced by £1. The plaintiffs applied several times to the defendant for payment, and on April 19th, 1899, issued a writ; but instead of claiming the whole amount they gave credit, in error, for a payment on account of £75, leaving a balance due of £50 5s. This mistake arose through the plaintiffs having been paid £75 by a person of the same name as the defendant in respect of another matter, which payment they wrongly credited to the defendant. After being served with the writ, the defendant paid the plaintiffs the balance of £50 5s. alleged to be due and the costs of the writ, and obtained from the plaintiffs a receipt showing that the whole of their account had been paid by him to them. The defendant forwarded the receipt to the architect, and was paid the balance due to him under the contract, including the full amount of the plaintiffs' account. The plaintiffs subsequently discovered the mistake which they had made and brought this action. On an application under Order 14 the Master gave the plaintiffs liberty to sign judgment for the amount claimed. The defendant appealed, and it was contended on his behalf that the present action would not lie, there having been a settlement of the plaintiffs' claim in the previous action. Mr. Justice Kennedy came to the conclusion that the defendant knew, when he was served with the writ in the first action, that he was being wrongly credited with a payment on account of £75, and he ought, acting conscientiously, either to have returned the £75 to the architect or to have paid it over to the plaintiffs. His Lordship held that the plaintiffs were entitled to recover the £75 as money had and received by the defendant to their use. A further point had been raised, that the payment of the money by the architect to the defendant made it money had and received for the plaintiffs, but his Lordship did not agree with this view. The money had been paid by the architect under a mistake of fact, and it was not received by the defendant on behalf of the plaintiffs. Judgment for the plaintiffs for £75, and costs.

Blocks of Flats as Houses: an Appeal Case.—The appeal case of *Kimber v. Admans* was heard on Friday last. The plaintiff and the defendant were owners of adjoining plots of land forming part of a building estate. Each plot was subject to a covenant not to build more than one house upon it. The

defendant proposed to build a block of flats upon each plot of land belonging to him. The plaintiff complained of this as a breach of the covenant and moved for an injunction to restrain the defendant from erecting these buildings. Mr. Justice Cozens-Hardy had refused the motion, being of opinion that each block of flats was one house only, and not a series of houses. The Appeal Court concurred in this decision.

Engineering Notes.

Electric Lighting at Leicester.—The Leicester Corporation propose to spend £100,000 on electric lighting. A Local Government Board inquiry has been held.

The King James Grammar School, Knaresborough, is being ventilated by means of Shorland's patent exhaust roof ventilators, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

The Baptist Chapel, Caerwys, Flintshire, has been fitted with the latest improved "small tube" hot-water heating apparatus by Messrs. John King, Limited, engineers, of Liverpool, who employed their well-known special economical coil heater with waterway fire-bars.

Gloucester Tramways.—It is proposed to take up the existing tramway lines at Gloucester, alter the gauge to 3ft. 6in., extend the lines to a total length of eight miles, and equip the routes for electric traction. The total cost of the scheme would be something like £95,000.

Stable Ventilation.—In the erection of the new stables for Mr. Marshall at Dobbie's Loan, Glasgow (Mr. L. B. Buik, of Glasgow, architect), great care has been taken to make the ventilation thoroughly efficient, the work being carried out by means of the new "Natural Exhaust" ridge ventilator supplied by the sole makers, the Climax Ventilating and Heating Co., Ltd., 93, Hope Street, Glasgow.

Euston Station Extension.—It is proposed by the scheme for enlarging Euston Station to close those portions of the carriage-ways of Drummond Street, Euston Street and Euston Square situate between Seymour Street and Melton Street, and to close Seymour Row, Melton Mews, Euston Place, Euston Grove and Euston Crescent; also, to close the part of Mornington Road between Stanhope Street and Serpentine Road, and to form a new road in lieu of it; and further, to construct an additional tunnel across the western end of Park Street, by Stanhope Terrace, Regent's Park. The ratable value of the property scheduled for acquisition is about £17,000.

New York's Tramway Power Stations are very large concerns. One which has just been completed by the Metropolitan Street Railway Company has a maximum output of 70,000 horse-power. This will be exceeded by the new station under construction by the Third Avenue Tramway Company, which will have a maximum capacity of 100,000 horse-power. The Metropolitan station, which is now in full working order, is 279ft. by 210ft., and the height of the engine room is 90ft. It has

a chimney 365ft. high, supported on 1,300 40ft. poles, the tops of which were driven 19ft. below high-water level. The chimney is constructed entirely of bricks, and about 3½ millions of these were required. Its entire weight is 8,540 tons. The foundation of the building rests on piles, upon which there is a concrete floor 5ft. thick. The system which this power station is intended to serve comprises 220 miles of track, almost all of which is equipped on the underground conduit system.

Incandescent Gas Lighting: Alleged Infringement.—On Thursday last, in the High Court of Justice, the case of the *Welsbach Incandescent Gas Light Company, Limited, v. the New Incandescent (Sunlight Patent) Gas Lighting Company, Limited, and Others* was heard. This was an action for an injunction, damages, and other relief in respect of alleged infringements by the defendants of the plaintiffs' patent (granted to Mr. Oliver Imray, and numbered 3,592 of 1886) for an improvement in an illuminant appliance for burners. Mr. Justice Buckley, in giving judgment, said the complaint of the plaintiffs was not as to the form of the mantles used, which was originally protected by a patent of 1885, which had now expired, but in respect of the use of the oxides of certain rare metals as brilliant illuminants in the making of the mantles. The patent was in respect of pure thorium or thorium oxide alone or in connection with other oxides. There was nothing about pure thorium, and what was then known as thorium was not pure, but consisted to the extent of 25 per cent. of other substances. He conceived that a mantle constructed according to prescription No. 1 in the specification of thorium, pure according to the knowledge of 1886, and which gave only three candles, or of thorium pure in fact, which would give only 1·3 candles, although it was worse as an illuminating appliance than the mantle of 1885, which gave 4 or 4·5 candles, was nevertheless better if it possessed in a greater degree the qualities of rigidity, durability, or stability. He might illustrate this by saying that in point of fact subsequent knowledge had shown that it was useful because, by the subsequent discovery that a small quantity of cerium would increase its luminosity, the step which was taken in 1886 had led to the possibility of making subsequently to 1893 a mantle which was not only durable and staple, but possessed also high illuminating power. Again, he might take another test of utility—that an invention was patentable which offered the public a useful choice. Now the patent of 1886 offered the public an opportunity of making with thorium an appliance which up to that date it had been suggested could be made only with zirconium, lanthanum, or yttrium, and, whether the thorium mantle gave a higher or lower illuminating light, it might well have been, and it was now known, that it was useful to give the public the choice of using that rare earth instead of some of the rare earths mentioned in the specification of 1885. His lordship then dealt with the question of infringement, which he also decided in favour of the plaintiffs, and gave them an inquiry as to damages, an order for destruction or delivery of the infringing articles, and the costs of the action as between solicitor and client.

TO MASTER BUILDERS, CONTRACTORS, AND ALL ENGAGED IN STONE & MARBLE CUTTING.

J. G. FAULDS'

IMPROVED

Multiplex Stone-Cutter.

*Any person manufacturing these Tools will be liable to
prosecution for infringement of Patent.*

THESE IMPROVED TOOLS for stone-dressing combine lightness with great efficiency in working, with perfect freedom from the annoyance of bad sharpening, tempering, or other defects. They possess *double* the advantages of the AMERICAN TOOTHED TOOL, by having, in a handy and convenient form, double teeth, or a chisel and "tooling drove" combined, the efficiency and economy of which a PRACTICAL MAN WILL SETTLE IN A FEW MINUTES.

SPECIAL NOTICE TO MARBLE CUTTERS.

These Cutters are now being specially Toothed and Tempered for the working of Marble.

Owing to the handiness and durability of these Tools they are in constant use throughout the whole of the United Kingdom

Two sample Tools, with six Cutters, sent carriage free to any address in the Kingdom on receipt of a Postal Order for 2s. to the

SOLE INVENTORS, PATENTEES, AND MANUFACTURERS—

An Architectural Causerie.

The Architect in Embryo.

THE writer of an article dealing with the vexed question

of pupilage and examinations in architecture lays himself open to the obvious criticism that what is new in his remarks is not true, and what is true is not new. This, however, can be said of most comments on most subjects; what the writer now wishes to do is to make a few remarks upon even so trite a subject as architectural training. For, with all due deference to those professional institutions and associations which have taken the education of the embryo architect under their wing, it can scarcely be contended that a satisfactory conclusion has been arrived at, judging by the class of work which is turned out from these schools by the pupils who have been attending them. The impression left upon the mind—after an inspection of exhibits of architectural students' work, such as those annually shown at Burlington House, the Institute, and elsewhere—is an appreciation of the beautiful draughtsmanship and the charming manner in which competitors "get up" their drawings, but a sense of disappointment in the designs so patiently delineated. In Mr. Bodley's criticism of the recent Institute designs the right note was sounded when he said he "did not think it much good to criticise drawings—theirs was not a drawing school, it was a school of architects. Drawing was not design, and they drew but poorly when they built magnificently." The President, also, in his address lays great stress on the primary importance of design. "Too great value," he says, "seems occasionally attached to the effect, technique, and execution of the drawing itself; and the quality of the architecture, a far greater thing, is sometimes, apparently, considered of secondary importance." One is bound to come to the conclusion that there must be something radically wrong with the existing form of architectural education for remarks such as those quoted above to be called forth from authorities like Mr. Emerson and Mr. Bodley when they address a body of students, remarks which seem to bear little fruit, judging by the quality of work annually exhibited. Let us consider whether the system of training does not help this state of things which, all deprecate and yet seem so powerless to stop. The old-fashioned idea of articling a pupil for a term of four to five years is denounced by all "advanced" educationalists—and with a measure of truth—as a system which supplies the architect with an office boy and a premium of some three to four hundred pounds, and ingrains into the mind of the unfortunate youth an instinctive dislike for anything and everything appertaining to the calling of architecture. Some educationalists would do away with pupilage altogether, whilst others would limit the term of articles to a year or eighteen months. In any case they are agreed that attendance at the classes of the Association and elsewhere is the proper way for the

student to acquire a knowledge of architecture. Straight from these schools the youth, as a rule, goes to the architect who will give him the most salary, in whose office he will have to trace, copy specifications, and do the usual drudgery of a junior assistant. Any knowledge of design he may acquire is haphazard in the extreme; the schools, however, have taught him to draw, and it is little wonder that he devotes all his spare time in making pretty pictures out of indifferent designs. It is obvious that the articling of a boy to an architect for a long period is a failure in most cases—from the point of view of the pupil. An architect who has sufficient work to entitle him to take a pupil has not sufficient time to teach him. Then again, as a rule the parent knows absolutely nothing about architecture, and should he select a good man to whom to article his son, it is more by luck than judgment. A

but seldom does, bestow upon the initial stages in a pupil's "articled" career, and he will be sufficiently advanced to design for himself midst the atmosphere of intelligent criticism from his chief and the assistants. The result of such a course, say, for a year or two, would be an absorption of design, instead of a perfection of draughtsmanship. This latter can be and should be acquired by all means, but it must take a second place in the training of a young architect. One may be asked, where does the examination come in the course which has been sketched out, and it must be admitted that one does not quite know. Possibly the pupil may have time to pass it, possibly not, but it really does not signify very much, and all that this article has attempted to suggest is some method in which the designing faculty could be improved—examinations are a luxury!

H. S. M.

system of education by classes or private teachers for the initial stages of the tyro's career seems manifestly advisable; but do not let this be the alpha and omega of his education. If he has a liking for his art—and one or two years' study will soon settle this point—he will himself be able to know with what sort of work he is most in sympathy; then let him enter an architect's office, not for a salary, not as an "improver"—detestable term—but as a paying pupil, who is perfectly capable of understanding and appreciating the quality of the work which is going on all round him, and able possibly to help in that work. He will have arrived at a time when he is independent of the individual attention and instruction an architect should,

Parham Hall. PARHAM HALL was formerly the seat of the first Earl of Orford. The existing remains of the Hall appear to be of the fifteenth century and are surrounded by a deep moat. There is a fine entrance gateway of the Tudor period, bearing the shields of the Orfords and Willoughbys, and of other past owners of the Hall. The building is now used as a farmhouse, and many of the original casements have been removed and modern sash windows substituted. The illustration of the Hall which we give on this page is from a drawing by Mr. Frederick Adcock.

"Ghosts" Again. In the general condemnation of the artistic "ghost" which is heard on every side (the subject was dealt with in our issue for January 10th last) there is, perhaps, one aspect of the question which is apt to be overlooked, but which merits consideration. The employer of the "ghost" is usually portrayed as a humbug, living on the reputation that belongs to another; a monster who fattens on the brains of the needy and genuine artist; while the "ghost" is regarded as a poor creature, caught between the devil and the deep sea, more to be pitied than blamed. This may be the truth, but it is by no means the whole truth. There would seem to be in this attitude of mind, too great a concern for the personal reputation and material interest of the artist, and too little for the broader interests of art; a disposition to put the artist before his art; or, perhaps, a certain tacit assumption that the worldly interests of the artist are identical with those of his art, which is not always the case. While it is impossible to defend any system based, as this one is, on fraud, yet if we consider the matter, particularly with reference to architecture, and more from the point of view of its interests rather than those of the architect—if we think the necessity of obtaining a good building to be the principal thing, and the money and reputation to be obtained by its erection to be a secondary matter, as it is—we must admit that much practical good is obtained by this system, which, in the present absence of public knowledge and appreciation, would probably not be gained without it. The erection of an important building is often placed in artistically incompetent hands. This custom is to be regretted—is, if possible, to be reformed; but while it obtains, as at present, it is distinctly to the advantage of the building that a man of some artistic ability should be engaged on its design. If he produces a fine building, it is a gain to art; if he loses the reputation thereof, it is simply a loss to himself. Should he stand out and let the bungler design it, or employ another bungler, the result is a discredit to art and no gain to anyone. The employer of the ghost is, perhaps, judged a little too harshly. He is no artist by nature, and cannot therefore be expected to look at things from an artistic standpoint. It is beside the mark to judge him by an artistic standard. He knows he is not deceiving the profession, and that his very existence proves that the public does not care. To proclaim on the housetops that he is not entitled to any credit for the design seems to him an unnecessary and ostentatious parade of virtue; everyone interested in the matter already knows it. Allowances should be made for a man in a false position. While everyone is entitled to such reputation as his work merits, yet he is a poor artist who must have the applause of the gallery ever ringing in his ears; and in these days, when the fame of the architect is, at its best, such a feeble thing, it is but a small exercise of self-denial to do without it altogether.

SUBSCRIBERS TO OUR SHILLING FUND, since the publication of our last list, will find their gifts acknowledged on page 56. Those who have not yet subscribed are also requested to turn to that page.

On Reflection.

The Late Mr. William Butterfield.

By the death, which occurred last Friday, of Mr. William Butterfield, F.S.A., the architectural profession has lost one of its most distinguished representatives. It is true that Mr. Butterfield's work was done many years ago, but his influence upon his art has survived, and will long survive his personal participation in it. He was the last survivor of that little group of architects who brought about the Gothic revival—a movement which has left a permanent impress on British architecture, and which, in spite of the excesses into which some of its exponents (Butterfield among others) were led, has done much to establish nobler and truer artistic ideals among architects of the present day. Mr. Butterfield was born eighty-five years ago, two years later than Welby Pugin and three years later than Gilbert Scott. His first important building was the Church of All Saints, Margaret Street, which was completed in 1859; but perhaps his most important and most characteristic work was the building of Keble College, Oxford. His work was confined almost exclusively to collegiate and ecclesiastical architecture. Among other buildings which he designed may be mentioned the chapel and school buildings at Rugby, the grammar school at Exeter, the churches of St. Albans, Holborn; St. Augustine, Queen's Gate; and St. Mary Magdalene, Enfield. All his work was characterised by sincerity, frank loyalty to fact, patience, and striking originality. With all his devotion to the ideals of a former age, he did not ignore modern requirements. He was an artist who never degraded his art, a man with a lofty and inspiring message to his age—a message which may be read in the buildings he has erected.

Architects and State Control.

THE question of Registration of Architects is one upon which professional opinion is very much divided, but the discussion of the pros and cons generally runs upon certain well known lines, the aim of the disputants always being to show how the proposed change will affect professional interests. Attempts may be made to look at the matter from the point of view of the interests of the general public, but, as in the case of all trade and professional discussions, it is only the lay person who can really take an unprejudiced view. For this reason it is well that whenever legislation is proposed in the interests of any particular industry, the non-technical press should hold, as it were, a watching brief on behalf of the public. We are glad, therefore, to note the interest which "The Liberty Review" is taking in the question of the Registration of Architects; though we feel bound to remark that if our contemporary is able to adopt an unbiased attitude as regards the different schools of architects it is hopelessly biased in another direction. The proposal being one for Government regulation the "Liberty Review" is opposed to it, as one more example of the onward march of Socialism, which it is its mission to withstand. It persists in treating the matter as a proposal for state or municipal control of architectural practice, instead of merely a proposal for a compulsory qualifying examination. Referring to our own attitude in the matter our contemporary says: "We should greatly prefer to see the architecture of the capital in the keeping of the BUILDERS' JOURNAL than in that of any State Department. Our contemporary would do the work much better." We bow to the "Liberty Review," but assure it that there is no likelihood what-

ever of anything that can fairly be called State control of architecture becoming an accomplished fact. Architects would resist, as strenuously as anyone, any proposals to curtail their liberty of action; what they desire—those of them who support Registration—is that the unqualified men who victimise the public and bring discredit on the profession, should be prevented from undertaking work for which they have neither the knowledge nor the capacity. It is true that no State machinery can endow men with taste or brains; if modern architects are such a feeble folk as our contemporary seems to think, Registration will not improve their quality, but neither will it rob them of any lingering artistic sense they may possess. The hall mark does not improve the quality of the gold, but it enables the uninitiated to distinguish between the real and the spurious metal.

Government and the Housing Question.

EVERYONE (except, perhaps, the "Liberty Review") will welcome the decision of the Government to take in hand the question of the housing of the working classes. The Bill introduced last week by Mr. Chaplin to amend the Act of 1890 contains two admirable provisions; local authorities are to be empowered to acquire land for building beyond the boundaries of their own area, and certain vexatious restrictions which have often prevented the putting in force of the provisions of Part III. of the Act (the part dealing with the purchase of land by local authorities) are to be removed. Beyond this the Government proposals do not go. A step in the right direction has been taken, but it is a very small step indeed. The evils of over-crowding are now so well known that further investigation is needless; the fact that in London alone nearly a million people are living under conditions which the law declares to be insanitary, yet is powerless to remedy, should in itself be sufficient to unite men of all political parties in a serious attempt to find a real remedy for such a dangerous and discreditable state of affairs. Nor is the housing problem one which affects only our great cities. As recent articles in the "Daily News" have shown, there are many country villages where the poor are as badly housed as in the vilest London slums. In 1884 the Prince of Wales, speaking in the House of Lords, expressed a hope that the result of the Royal Commission on this subject, which was then appointed, would be "to recommend to Parliament measures of a thorough and drastic kind, which may be the means of ameliorating not only the dwellings of our poor, but their condition generally." Those thorough and drastic measures have not yet been forthcoming, though the need for them is far greater now than it was sixteen years ago. There are those who believe that no real improvement is possible without a radical reform of the land laws; but to proceed on that line inevitably means bringing the subject into the arena of party strife. There is more hope, it seems to us, of practical good being speedily accomplished, if the subject continues to be discussed, as it has been hitherto, as one in which it is possible for both parties to act together. Mr. Chaplin's bill should be accepted as far as it goes, and an effort made to strengthen it. The slum landlord who fattens on the degradation and misery of the poor is not a sympathetic figure, and we see no reason why a clause should not be inserted in the Bill with the approval of all parties, to compel him to reveal his identity and to submit to the destruction of his property without compensation if he will not keep it in a sanitary condition. The scandal of our existing system is that the nefarious trade of the slum landlord is such a profitable one; we must make it unprofitable.

GATEHOUSE AT SLAUGHAM PLACE, NOW AT
CUCKFIELD PLACE. DRAWN BY C. G. HARPER.

SLAUGHAM PLACE.

By C. G. HARPER.

DEEP down in a hitherto sequestered nook in the weald of Sussex stands the little village of Slaugham, sheltered from the north winds by the ridge of high ground, running east and west, on which the hamlet of Hand Cross is built. The old coach road between London and Brighton runs through Hand Cross, which indeed arose into being as a hamlet from that fact, and goes in breakneck fashion downhill in two branches: one by way of Hickstead, the other through Staplefield Common. In the angle between this fork of the highway and that of yet another road branching off to the right hand to Horsham lies Slaugham, three miles from the nearest railway station of Balcombe, where few trains stop, and six miles from the more convenient junction of Three Bridges.

The stranger enquiring in these parts for Slaugham, and pronouncing the name as spelled, will probably not be understood of the natives. "Slaffam," on the other hand, wins to instant recognition. The derivation of the place-name is hinted at in the original spelling as set forth in the *Liber Regis*, "Slougham-cum-Crolé." "Crolé" is the Crawley of to-day, six miles distant. "Slougham" is an excellently descriptive spelling, for the village is built on the very margin of the sloughs that mark the headwaters of the Arun, the Adur, and the Sussex Ouse, and it was in the very midst of these morasses that the once magnificent mansion

of Slaugham Place was built. A true exemplar, this spot, of that Sussex of which a barrister on tour through the county in 1690 writes to his wife: "I vow 'tis melancholy consideration that mankind will inhabit such a heap of dirt. The Sussex ways are bad and ruinous beyond imagination. The county is in a sink of about fourteen miles broad, which receives all the water that falls from the long ranges of hills on both sides of it, and not being furnished with convenient draining, is kept moist and soft by the water till the middle of a dry summer, which is only able to make it tolerable to ride for a short time."

These conditions make the ruins of Slaugham Place what they are to-day. Low down, in a watery meadow, they stand, the long-deserted home of the Coverts, a vanished family once among the most powerful as they were also of the noblest, in the county. The Coverts were of Norman descent. They, to use a well-worn phrase, "came over with the Conqueror"; but it is not until the close of the fifteenth century that they are found

yard to hall, but, doorless, with its massive stones wrenched apart by the clinging ivy, stands merely as some sort of key to the enigma of ground-plan presented by walls ruined in greater part to the level of the watery ground.

The measurements of the building are 175 ft. by 133 ft.; those of the inner court are 80 ft. square; of the Great Hall, 54 ft. long by 30 ft.; of the kitchen, 35 ft. square, with a great fireplace 13 ft. wide. A tradition still lingers in the neighbourhood that the establishment numbered seventy servants. The singular facts of high wall and moat surrounding a mansion of Jacobean build seem to point to the existence of an earlier building provided with these defences in days when men thought of security first and of comfort afterwards. Some few mullioned windows of earlier date than the rest of the building remain to confirm the thought.

That a building of the magnificence attested by these crumbling walls should have been allowed to fall into decay so shortly after its

RUINS OF EAST FRONT, SLAUGHAM PLACE. DRAWN BY C. G. HARPER.

settled at Slaugham. They were preceded as Lords of this Manor by the Poynings, of Poynings, and by the Berkeleys and Stanleys. Sir Walter Covert, to whose ancestors the manor fell by marriage, was the builder of the grand mansion, whose ruins yet remain to show the almost palatial character of his conception of what was due to a magnate of his status. They cover, within the ancient walls of red brick which encompass the grounds and rise from a still partly-filled moat, over three acres of what is now orchard and meadowland. In spring the apple trees bloom pink and white amid the grey and lichened ashlar of the ruined walls of Palladian architecture; and the lush grass grows tall around the cold hearths of the roofless rooms. The noble arcaded entrance leads now, not from court-

completion is a singular fact. Although the male line of the Coverts failed, and the estates passed by the marriage of their womankind into other hands, yet their alienation would not necessarily imply the destruction of their roof-tree. The sole explanation is to be sought in the situation and the defects of the ground upon which the building was erected; a site no builder of to-day would think of selecting as suitable for so important a dwelling. Home as it is of swamps and damps, and quashy as it is even now, it must in the past have been the breeding-place of agues and chills innumerable. An ideal spot, possibly, for defensive purposes, but for domestic use not to be thought of.

Such soft and shaky earth as this could not bear the weight of so ponderous a structure as was Slaugham Place; the oozy ground subsided and pulled its masonry apart and rotted its fittings. Despairing of victory over the reeking moisture, its owners left it for healthier sites. Then the rapacity of all those neighbouring folk who had need of building material completed the havoc wrought by natural forces, and finally Slaugham Place became what it is to-day. Its clock tower was pulled down and removed to Cuckfield Place, where it now spans the drive to that romantic domain. Its handsomely-carved Jacobean stairway is to-day the pride and glory of the Star Hotel at Lewes.

The Coverts are gone; their heraldic shields, in company with an architectural frieze of greyhounds' and leopards' heads, and skulls of oxen wreathed in drapery after the Palladian manner, still decorate, beneath the enshrouding ivy, the remains of the north entrance of their mansion, and their heraldic achievements are repeated upon their tombs within the little church of Slaugham, upon the hillside. You may, if versed in heraldry, learn from their quarterings into what families they married; but the deeds they wrought, and their virtues and their vices are for the most part clean forgotten, even as the name of them is gone out of the land, who once, as tradition has it, travelled southward from London to the sea on their own land. The

SLAUGHAM PLACE; RUINS OF GRAND ENTRANCE ON NORTH FRONT. DRAWN BY C. G. HARPER.

efforts, a better grasp of the method of construction, if he first draws the work to scale. The annexed illustration (Fig. 1) will explain the method of setting out and drawing the main parts. To set out a Doric portico or frontispiece, first draw the base line A B, and erect the perpendicular line I H, and on this mark the height of the first or uppermost member of the horizontal cornice as at H, according to the number of diameters in the order. Divide the entablature into its three parts, viz., architrave (composed of two fasciæ, with a fillet also termed 'tenia'), the frieze, and the cornice. A triglyph, P, is always placed over the columns, and its breadth is equal to half the diameter of column at its base. The distance between the triglyphs is generally equal to the height of the frieze, therefore square. In some examples there are various numbers of triglyphs placed between those over the columns according to the length of cornice, but in this example there are three. The intercolumniation for the three triglyphs, according to the scale of this order, is five diameters, that is, the distance from the central line C E to the central line D F. The intercolumniation being found, take half thereof between the compass, and, setting one foot in the point I, make a point at each side upon the line A B at C and D, and then erect the perpendicular lines, C D and E F for the central lines of the columns. The triglyphs are spaced out on the base line A B as follows: Take fifteen minutes, the half breadth of one of the triglyphs between the compass, and make a mark on both sides of the point C as *a*, *b*, and on both sides of the point I, as *e*, *f*, and on the point D make two points as *c*, *d*. Now take forty-five minutes, the height of the frieze (which is the width of the metopes) between the compass, and place one foot on the point *f*, and make a point as at *h*, and then from the point *e* make a point as at *i*, from *g* to *h*, and also from *i* to *k*, which is the width of a triglyph. It will be seen that this method gives the width and positions of the other triglyphs as *ab*, *fe*, and *cd*. These widths and positions are then transferred from the base line to the frieze, working from the centre lines of the portico and columns. The width and positions of the metopes are regulated by the triglyphs. The height of the members of the cornice are set on the centre line of the column from the point *f*. The two upper lines that make the square of the cyma-recta are omitted because of the circular cornice mitring to the level returned cornice. The projections are taken from the centre line of the column. To find the pitch of the pediment, set one foot on the point H, extend the other to G, and then turn this foot to the centre line I H, and make the intersecting point O, which is the centre for the circular pediment, also termed a compass pediment. The same rule is also used to find the centre for a raking or angular pediment, as shown by the dotted line R to G.

"The spaces between the triglyphs are called metopes, and are generally filled in with some ornament. In some antique examples the metopes are alternately enriched with ox-skulls and with patera, but they may be filled in with any other ornament of appropriate form. The method of drawing the triglyph, guttæ, and panel with patera is further elucidated by the annexed sketch (Fig. 2), which shows the

elevation and section, with the parts figured, and is self explanatory. The guttæ or drops in this example are pyramidal in form, but in many examples they are conical, being cones or parts of cones. The soffit of the corona is often enriched. These enrichments should be sunk up, and never drop lower than the line of the soffit. Three forms of mutules, a 'centre' and 'rights' and 'lefts' (as shown in Fig. 1) are required for the circular cornice, so that their sides will be perpendicular and rake with the sides of the mutules on the horizontal cornice. The 'rights' and 'lefts' require to be specially made. The centre one may be obtained from the casting mould of the mutules

cornice, which sometimes happens if the latter is run first. For small work, the horizontal cornice and the architrave are run first. This is done from a parallel running rule fixed on the frieze. If the work is large, fix two running rules on the frieze, one for the cornice and one for the architrave. In both cases a running rule is required for a bearing for the ribs of each running mould, one fixed on the weathering at the top of the cornice, and one on the soffit of the architrave. After the mitres are "put in," the tympanum is fined, and then the mutules and triglyph are fixed. The upper surface of the pediment and the portico is fined as soon as the mould of the cast part is taken off. The

FIG. 1.—SETTING OUT AND FORMING A DORIC PORTICO.

for the horizontal cornice by bending it to fit the curve of the circular cornice. The front and sides of the mutules are sometimes enriched by a series of dog-tooth sinkings, as shown by the centre mutules and two external ones.

"The method of forming a portico in Portland cement is as follows:—First form vertical screeds on the walls close to the outer sides of the columns, taking care that they extend from the plinth of the column to a little above the level of the apex of the pediment, then fill in the plain intermediate spaces and rule them off, using the vertical screeds for bearings. On this surface set out the full size of the main parts of the work to be done. All measurements should be taken from the centre of the portico. This centre line is obtained from the centres of the columns, as described for the setting out. If the work is large, or the pediment to be run, the circular cornice or angular cornice, as the case may be, should be run first, so as to save long mitres, also to prevent stuff falling on the horizontal

columns and the soffit of the architrave are next formed, the former being carried out in a similar way as described for diminished columns."

Carnarvon Improvement Scheme.—A large improvement scheme has been adopted by the Carnarvon Town Council. It contemplates the demolition of three insanitary areas, and the erection on them of working class houses. The total estimated cost is £18,418.

Housing at a Profit.—A return of the income and expenditure for the past year in respect of the dwellings for artisans and labourers erected by the Liverpool Corporation has been issued. From the Victoria Square dwellings, which consist of 272 tenements and twelve shops, there is a net income of £1,613 17s. 11d. The Juvenal dwellings, comprising 100 tenements and one shop, produced a net income of £537 3s. In the Arley Street dwellings are 34 tenements; these give a net income of £273 11s. 4d. Gildart's Gardens dwellings—88 tenements—brought in a net income of £340 1s. 11d. St. Martin's Cottages consist of 134 tenements, and have realised a net income of £86 1s. 8d.

ARCHITECTURAL ASSOCIATION.

The Exterior Treatment of Sharp or Acute Angles in Street Buildings.

By A. W. HENNINGS.

A MEETING of the Architectural Association took place last Friday evening at No. 9, Conduit Street, Regent Street, W., the chair being taken by the President, Mr. G. H. Fellowes Pryne. The minutes of the previous meeting having been read and confirmed, the following gentlemen were unanimously elected members of the Association:—Messrs. E. G. Cole, J. H. Peacock, J. Bruce Merson, A. Wingate, H. G. Coyne and J. H. Watkins. The president announced that Messrs. L. Cabuche and F. E. Ravenscroft had been reinstated as members. A vote of thanks was then carried to the architects who had permitted the members to go over their buildings at the first Spring Visit on February 10th: to Messrs. Alfred Waterhouse and Sons for the visit to the University Hospital Extension Works; and to Messrs. A. Dunbar Smith and C. C. Brewer for permission to visit the Settlement, Tavistock Place. On the motion of the president, a vote of thanks was then given to Mr. W. H. Seth-Smith for his donation of ten guineas to the Library Fund. Mr. A. W. Hennings then read his paper, which was illustrated at the close by a large number of photographic lantern views which he criticized:—

The subject of this paper, "Exterior Treatment of Sharp or Acute Angles in Street Buildings," may seem to some rather far-fetched, and indeed it is hardly one that comes in student or class days, but sooner or later, when you get into active practice, you will have a site that is not right-angled, one whose prominent corner is much less than a right angle, and then you will find it indeed a difficult problem. First of all, the plan will trouble, for it is very obvious that the sharp angle is of no good to you—the ground enclosed is so small that it is clearly a waste of material to enclose it with bricks and mortar, and yet in a town the land is so valuable that the owner naturally does not like to sacrifice a square foot without a very good reason. Then, again, the very prominence of the angle seems to fit it especially for a business entrance; but whilst its position is apparently so suitable for that purpose, it is clear that an entrance so placed must mean long passages and consequent waste to reach the farthest parts of the building. I do not propose to-night to follow up this question of plan of the structure beyond the angle, but mention it in passing as one of the factors that will have to be considered. My attention to the subject was caused in the usual way, by having to design various buildings to fit angular sites. After a few attempts it struck me that the best thing to do was to carefully observe what had been done in such instances and I was somewhat amazed to find how many times the problem had been attempted, and also that very few of the attempts could be called really successful. The recent cutting of important new streets through old localities has resulted in the formation of many difficult sites, and, after carefully looking at the various treatments, I have come to the conclusion that they all fall under one of two heads:—Firstly, the architectural lines of the two façades are simply returned across the sharp angle; and secondly, a distinctive treatment to express the angle.

Now, the first method is the easiest and cheapest. It is, therefore, most generally used, and, although it is really an avoidance of the problem, it is not therefore bad; and as long as there is only a flat roof to the building there is no difficulty, but directly a pitched roof is required it is easy to see that the junction of the ridge running parallel to each front must meet at a great distance back from the angle, and will want something to mask it, whilst if the angle enclosed is so small that one roof only can be used for a covering, the result will be a ridge running towards the broadest part, and I venture to think it will pass the wit of

man to make such a roof presentable on the exterior.

To return to the plan. The first thing that suggests itself is to cut off the useless point—in fact, to truncate the angle—and the amount so cut off will depend chiefly upon how much land your client is willing to sacrifice. If it is only a little there will be only a narrow face to treat, and possibly the best thing for this is to carry the strings and cornices round and vary the windows, but it is surely the most bald way of treating it by simply cutting off the angle. The right thing to do seems to be to make a small return at right angles to the façades and then to fill up the intervening space with a wall at right angles to the bisection of the angle. This at once gives interest, and not only satisfies the eye with proper mitres to the strings and cornices, but serves a second useful purpose by well enclosing any detail put on the end. Do not in any case put a distinct feature on to the end unless you so enclose it—for the inevitable result is that this feature will look stuck on and not grow, as it should, out of the structure.

If, however, a considerable angle can be cut off so that there is a reasonably wide face to treat, you will at once have room for special features if the site and purpose of the building warrant it; but the before-mentioned right-angled returns to the façades are absolutely necessary to enclose and mark it.

Another way is to sacrifice the point and join the two façades by means of a curve. This is the most popular way to judge by the number of times it occurs in our streets, and any treatment of this must be ruled by the smaller or greater radius of the curve. If small, there is very little scope, and perhaps the best thing is to simply run the strings to cornices round it; but this requires care. Again, the necessity of right-angled returns to the façade must be borne in mind; the curve is so much more clearly defined by their use, and the breaks, be they small or great, at once give a chance to enclose a special feature. Still another way to enclose the curve is by means of projections taking the form of pilasters or strips, and there is a very notable example of the bold effect of this treatment in Mappin and Webb's premises at the junction of the Poultry and Queen Victoria Street.

There are also examples, and good ones too, where there is no break or mark, but the effect there seems to have been produced by reason of the great size of the curve, and it is really the façade continued and can hardly be called a treatment of an angle site. Returning to the smaller curve, the natural growth upwards seems to be towards some sort of turret and it is in this that there are so many failures. So long as the features are inclosed by the lines of the building they are kept in their places, and unless very strange and uncouth do not greatly offend. But directly they get clear and are outlined against the sky, and have to be judged on their own merits, the difficulty begins. Here, it may be remarked, that no amount of ingenuity displayed in the formation of a turret by transitions from octagons to circles and back again, with all sorts of cunning and spicy detail, will atone for the lack of pleasing outline. Many of the competition designs published in our technical journals show this extreme cleverness, but when any of them are carried out somehow the result is not so good, and with humiliation one has to confess that the sober, simple outline to be seen on so many stable turrets erected during the last century are much more satisfactory than the clever but laboured productions of the present day. They are to my mind products of that unrestfulness so typical of the times.

As to the window treatment of the curve, the size must determine how many windows there shall be at each level. If very small, a blank end will probably be best, for lintels or arches put on a small curve have a very uncomfortable and weak look from certain points of view. This is, perhaps, a truism, but you will find modern examples of the error.

There are some very satisfactory treatments where a pier is at the centre of the face of the curve with windows each side, and certainly the effect is strong—it seems to efficiently

buttress the angle. The introduction of a doorway at the base of the curve does not seem very desirable, although it is frequently done, but it tends to weaken the appearance, and its details will inevitably break the clean sweep of the curves.

Another point for consideration in the treatment of an angle or of a curved end is—how many of the horizontal features of the façades should be taken round or across it. Some are necessary to tie it in, but if all are taken across the result seems to be merely a continuation of the façades, and it will, I think, be very clearly seen that the most successful of the designs are those where the principal and strongest features are used, the subsidiary ones being stopped by a pier or return.

In City buildings, however, the most difficult place to treat properly seems to be the shop front. If there is no door the angle is obviously a splendid place for the display of goods, and piers sufficiently substantial to satisfy the eye are seldom allowed. This is a lamentable fact, but still it is a fact that you will have to deal with, one that will cause you much trouble. To ignore it, and treat the building as a design only above the shop cornice, is weak, but it is the course usually followed, and to judge such designs you must see them when the shutters are up, when a solid base sufficient to support the superstructure is apparently formed. An answer to this objection is that when the shops are in use the streets are so crowded that this defect is hidden, but surely it is always possible to bring some strong line down, and the right-angled returns to the façades before advocated will here serve a very useful purpose.

In domestic or office designs it is nearly always possible to get a strong base, as, for example, the delightful corner at the Institute of Chartered Accountants, where the stonework of the base is not only carried right round the curve, but its appearance of strength emphasised by means of horizontal rustications.

There is yet another way of treating the angle, and that is to so mask it that it is impossible to know that it is an acute angle. This is hardly a commendable thing to do, but there is an important example in the Bank of England at the corner of Princes Street and Lothbury. If it were not for the tanks above the attic storey you would not guess that the angle was less than a right angle, whereas it is really very sharp. No one can deny its cleverness, but it does not seem to be on right lines.

The City abounds in various angular treatments, and honest criticism must admit that many of them are very clever indeed; there seems to be no lack of imagination in them, and oftentimes they must be judged by their design and not by their detail. The latter is often bad—very bad, and would disgrace our Elementary Class of Design—but there the design is, and as such it is to be criticised. The City is, indeed, a glorious school for study, and is a great example of the truth of the old tale of "Eyes and no eyes." To those who have learned the language the streets become, as it were, an open book, wherein something good and useful can always be read, but how many of us do so? A rush from the train to the office in the morning, and another rush back in the evening gives one but a blurred idea of what is to be seen. But go up to town one fine summer's morning—say, between four and five, before even the workmen begin to get about—and you will be astounded at the wealth of design there is to be seen when all the streets are quiet, and you can stand to look at a building without attracting a crowd. Then you will find the charm of London and at once come to the conclusion that many cities we rush to see on the Continent are not to be compared with ours—not even for picturesqueness. What glorious sketches many of the streets would make, and perhaps some day we may even get some in the Association Sketch Book.

Mr. H. D. Searles-Wood proposed a vote of thanks to the lecturer which was seconded by Mr. W. H. Seth-Smith, and supported by Messrs. S. F. Clarkson, Booth, G. B. Carvill, Matt Garbutt, C. H. Brodie, and G. H. Fellowes.

Prynne. The motion was then carried unanimously, and Mr. Hennings replied. The chairman announced that the next meeting of the Association would take place on March 9th, when Mr. C. E. Bateman would read a paper on "Small Houses." The meeting then terminated.

Travel: Part of an Architect's Education.*

By CHARLES OWER.

TRAVEL is as necessary a part of the architect's education as drawing or mathematics, and students of the fine art of architecture must not forget that it is necessary to be strong, healthy, well-educated, and gentlemanly in manner, to work hard, and to be content with nothing less than the best. Our student must have the faculty for taking infinite pains, and be possessed of a strong body and a healthy mind, with the elements of a liberal education ground into it. This being so, an architectural student should spend, at least, half his leisure time in the open air cycling, sketching, botanising, examining the quarries and the buildings in progress in his district during the summer; and in winter he should dance, skate, hear good music, and read the best literature, in order to become a cultured man, which, in the opinion of Matthew Arnold, can be attained by reading about five hundred books, which give a knowledge of the best that has been thought and said in the world. The other half of the student's time outside the office should be devoted to scientific and artistic evening classes.

The architect should know something about everything, and as much as possible about his profession—"Age cannot wither nor custom stale its infinite variety."

Architecture is an art which has come down to us from the earliest ages, and if we are to learn by the works of the great masters we must go to see these works. It is impossible to appreciate a great picture by looking at photographs or engravings of it, and the conditions which affect the study of a great building are much more complex than those of a picture. A picture can be seen in one light only, the building in many. The building changes in the course of years, but the picture remains the same. A building is affected by its surroundings, and the picture is not; yet, there are some persons who would recommend a painter to travel, while regarding this as unnecessary for the architect. Such persons never get their ideas expanded beyond their local prejudices, for it will be found that all our leading men travel, sketch, and read. In all time past this has been the case, else how do you account for the spread of great architectural ideas in ancient times—where did our rounded and pointed Gothic arches come from? Certainly not out of our soil. Where did our grand cathedral architecture come from? Not out of the North. No. All our architectural ideas came, like our religion, from the Far East—brought to our shores by men who travelled when few did so. At the present time travel is more than ever a necessity. How do you educate an artist?—by showing him fine paintings; how a sculptor?—by allowing him to see the finest ancient and modern statues; and how an architect can be educated without seeing fine buildings, I do not know. It becomes us, therefore, to enquire—(1) Why should we travel? (2) How should we travel? (3) When should we travel? (4) Where should we travel? (5) What should we do when travelling?

Why should we travel?

The fact that travel enlarges a man's mind, gives him new ideas, makes him more catholic, is too well known to need much emphasis. But, in addition, there are reasons which are very special to the student of architecture.

It has been the universal necessity of our profession to sketch, and every man who ever

reached a reputable place was draughtsman sufficient to express his ideas in the form of perspective sketches of the forms he saw in his mind's eye. But this faculty was not gained by mere office work; it was fostered by the drawing of natural objects and buildings. These studies should not stop at ancient buildings, but should include any good modern work. In any case details and mouldings can only be appreciated by close examination and measurement on the spot.

In the usual routine of an office training, a man gets into certain ruts, styles, or tricks of design, which is a dangerous state, leading to conceit and all kinds of trouble and to the idea that if a man can make a fairly good drawing he is therefore an architect. You all know the kind of man, and there is no cure for him but travel.

An architect should also know something of the other fine arts, and should have seen the great art masterpieces, which, as a rule, are in the neighbourhood of fine buildings. These are some of the special reasons why the architect should travel.

How should we travel?

This part of my subject naturally includes the preparations for travel. Now I consider that the great preparation one has to make is the preparation of oneself—the preparation of the mind. So far as I know this can be best done by reading first the best books dealing with the subject generally, such as Ruskin's "Stones of Venice," "Seven Lamps of Architecture," and the various books referring to the particular district or place to be visited.

Nothing makes a tour so charming or profitable as this kind of preparation, and if you are engaged in studying a building or district of which you know the history, it makes the whole place live. I would recommend to you for a simple experiment to go and see Stirling, Dunblane, and Doune, and then to take a good map and go to the hill behind Callander and trace the course of the stag in "The Lady of the Lake." How much more you can get out of Florence and Venice after reading Ruskin, Romola, "The Makers of Florence," "The Makers of Venice," and from Rome after Marion Crawford's "Ave Roma Immortalis," and Hare's Walks, those only who have done it can know. Therefore, I say, read well before you start. Your kit need not exceed about 40lbs. in weight.

Leaving all minor details to yourselves, a word about colours. Water colours are most commonly in use, but I prefer Creta Lavis pencils, an ounce of fine turpentine, a stump to spread or blend the colour, and a scrap of emery paper to clean it. Out of a case of pencils containing twelve colours, including white but no black, costing 2s. 9d., and weighing with the case 4ozs., I can get results, better, quicker, and with less trouble than when I used water colours.

Nowadays the bicycle is one of the handiest means of getting about in one's own district, and it is a good and economical way to spend a holiday to fix on a good architectural centre, and from it work the surrounding country. Brechin, Stirling, Linlithgow, Dumfries, Kelso, Durham, Lincoln, Oxford, and Cambridge are all suitable for this system of working in this country. Then in an architectural cycling tour (which should cost about ten shillings per day all told) you may select a route which will include a sequence of interesting buildings. One of the most interesting tours in this neighbourhood is to visit the residences of the ancient Scottish monarchs. Beginning at Falkland, in Fife, you can go through Kinross to Loch Leven, where Queen Mary was imprisoned, to Dunfermline; then to Edinburgh, Linlithgow, Stirling, Doune, Scone, Perth, and home. All along the route you will find matter for your sketch-book, beautiful scenery, and historical buildings. Don't forget to read your history of Scotland before you go, and Grant's "Yellow Frigate." Fife is full of quaint bits in Crail, St. Andrews, St. Monans, Strathmiglo, Culross, &c. I am inclined to think that in going from city to city the quickest way is always the best, so that you may have plenty of time to go slowly at the places where you

work lies. It may not be out of place here to say that travelling costs more the older you become.

When should we travel?

My answer to that is, as often as you can afford it, but especially when you are young. I maintain that parents or guardians who desire that their charges should have sufficient education to take a place in the front rank of the architectural profession must furnish the young man with sufficient means to travel for at least three months during the course of his apprenticeship. I calculate this would cost about £50. The present system produces students without zeal and practitioners without love for their art, because in their youth they are not made aware what a glorious and inspiring art they have the privilege of following. Therefore, I say, travel when you are young, enthusiastic, and before the stern necessities of business have increased your responsibilities.

Where should we travel?

Anywhere where there is good architecture. What you want is to get your view extended beyond the environment you are in all day and every day. See Edinburgh, Glasgow, Aberdeen, Peterborough, York, Chester, Oxford, Cambridge, and their environments; then Normandy, Paris, Germany, Italy, Spain, Berne, and Fribourg in Switzerland, and, if you are born wealthy and lucky, there is the mysterious East, with Egypt and India after that. Any place where civilisation and the Arts have grown old together, there you will find what you seek, if you seek aright. From Japan to Kirkwall you will find that men in all ages have had ideas worthy of your attention. By such means you will release yourself from hackneyed forms, and your work will be interesting and original. You will not be tempted to repeat one form of roof *ad nauseam*, nor do just the same as your apprentice master did under conditions which have much improved since he wrought.

What should we do when travelling?

We should sketch, take notes, and photograph anything that strikes us as uncommon, picturesque, or beautiful, not forgetting to make plans and use colour to elucidate our meaning. There is not time nowadays to sit down before a building and make a drawing of it, when with a Kodak you can get a sufficient view of the building in a fraction of a second, which, conjoined with sketches of the mouldings and a thorough examination of the plan, should be sufficient. To sit down to sketch an elaborate house is a splendid exercise, but it is not business, any more than frontal attacks are admissible in modern warfare. To become enthusiastic over architecture you must have seen it, and to really see it once through the proper eyes is always to love it. But you must go out into the world to see it, and to do that you must travel.

Rebuilding of Highgate Archway.—The rebuilding of Highgate Archway is practically completed. All the girder work is finished; the old stone and brick arch is rapidly being demolished and will soon be a thing of the past.

Stockport Infirmary.—The Diamond Jubilee wing (estimated to cost about £12,000) has made but slow progress during the last twelve months owing to the building trade disputes, but it is hoped that the new building will be ready for occupation this year.

The Provident Institution of Builders' Foremen and Clerks of Works has just issued its annual report, which shows the excellent work this institution is performing. The amounts paid for pensions to men and women have been increased, with a corresponding increase in the total expenditure, which, considering the great good affected by this fund, should be quickly made up. During last year the sum of £366 12s. was expended, making a total of £10,331 13s. 6d. expended in pensions for the last forty-nine years. Subscriptions and donations should be sent to the treasurer, Mr. J. Stapleton, 35, Aytoun Road, Stockwell, S.W.

*Résumé of a paper read before the students of the Dundee Institute of Science and Art, on February 24th, 1900.

A LARGE BRIDGE COMPETITION: PREMIUMS, £1,500.

By JOHN PLUMMER, SYDNEY, N.S.W.

THE Australian colonists, like their American kinsfolk, manifest a preference for doing things on a big scale whenever possible. In Sydney the citizens possess the largest organ and one of the largest town halls in the world; while north and south of the city are two of the largest public pleasure reserves to be found in any country outside the United States. The Hawkesbury River, of which the people of New South Wales are as proud as of the famous Sydney Harbour, is spanned by an immense railway bridge, the largest of its kind in the Southern Hemisphere, and, as regards foundations, a most remarkable one. The actual length of the bridge between the abutments is 2,900ft., and it is supported by six piers, each resting on a caisson filled with concrete and forming a solid foundation. The caissons are respectively 101, 155, 146, 147, 144, and 162ft. in depth, these different measurements representing the inequalities in the depth of the river; the last-mentioned caisson being the deepest known foundation for a bridge. The main girders are 410ft. long from centre to centre of bearings, the height of the principal girder being 58ft. above the surface of the river. Each span was constructed on a large pontoon, 335ft. long, 61ft. wide, 10ft. deep, and provided with staging sufficiently strong to bear the whole weight of the immense mass of ironwork, and high enough to enable the span, on the pontoon being floated at high water into position, to clear the tops of the opposite piers, on which the girders rested when finally in place. After the span was ready the water was pumped out of the pontoon and it was towed into its destined position between the two piers on which the span was intended to rest. As the tide fell, each end of the span descended into its proper place, and the pontoon and staging, released from the ponderous load, floated back to the gridiron. The bridge was formally opened for traffic on May 1st, 1889. The New South Wales Government is now entertaining an even more ambitious idea, that of connecting the northern and southern shores of Sydney Harbour by a bridge, which, under any circumstances, must be one of the highest and longest in existence. Such a structure has become a pressing necessity, but although its importance has been recognised by successive ministries, that of which Mr. Lyne is the head has been the first to take practical action in the matter by offering a couple of premiums, one of £1,000 and another of £500, open to all the world, for the most suitable designs for the required bridge. The designs must provide for two footways each 10ft. wide, two roadways each 20ft. wide, or one roadway 40ft. wide, also for a width of 24ft. in the clear for a double line of railway. It is considered that the bridge should be a single-tier bridge, as the extra height to be surmounted by the railway or road, as the case may be, might be an objection, but designs showing either the footways or the roadway, or both, overhead, may be submitted, and will receive consideration. The bridge must consist of a single span, and a clear headway of 180ft. above high water, for at least the middle 600ft. of its length, must be provided. The structure must be designed to carry a live load of 130lbs. per superficial foot of roadway and footpath, and every part of the roadway is to be capable of carrying a moving load of thirty tons on two pairs of wheels, and for a train on each line of railway consisting of three of the heaviest class of engine and tender in steam, followed by loaded trucks. The engines and tenders to be taken as weighing 110 tons, with a length of 55ft.; and an axle load on drivers of eighteen tons, the distributed load due to the loaded trucks to be taken as one and a half tons per lineal foot. The competitive designs will have to be delivered in Sydney not later than August 1st, 1900.

"BUILDERS' JOURNAL" SHILLING FUND.

AN OFFER TO COLLECTORS.

A SPECIALLY gratifying feature in connection with our Shilling Fund has been the way in which many of our readers have made use of the collecting forms we issued to obtain subscriptions from their friends or fellow workers. We feel convinced that a great deal more might be done in this way, as there must be many thousands in builders' workshops and architects' offices throughout the country who would willingly give a small donation to such a worthy cause if a personal request were made to them, though possibly they would not take the trouble to send off a contribution on their own account. In order to encourage those who have begun to collect and to enlist the services of many fresh collectors, we have decided to present a copy of the latest issue of "Specification" to every contributor or collector of twenty shillings and upwards. "Specification" is becoming more and more widely known as an invaluable book of reference for architects and builders; it is published at 5s. nett, and contains a vast amount of conveniently arranged and thoroughly reliable information on an immense variety of subjects relating to architectural and building practice. This offer applies equally to those who have already sent in their contributions; if they wish for a copy of "Specification" to be sent to them, will they kindly send us word to that effect? Donors of smaller sums than twenty shillings may, of course, make themselves eligible for this gift by sending in the amount of the difference.

The following subscriptions have been received since the publication of our last list:—

	Shillings.

The following additional gifts in kind have been received at the offices of the Executive of the Gift:—

Messrs. Shanks and Co. (Barrhead, near Glasgow).—The entire Sanitary Fittings for one Home.
Messrs. Drew-Bear, Perkins and Co.—Sixteen 25-foot Steel Joists.
Messrs. Richard Moreland and Son.—The Steel Principals for the Recreation Hall.
Messrs. Dorman, Long and Co.—Sixteen 25-foot Steel Joists and 50cwt. Steel Lintols.
The Edison and Swan United Electric Co., Ltd. (per Mr. Max Byng).—Electric Lamps and Holders for all six Homes.
Messrs. Sharp, Jones and Co. (Parkstone, Dorset).—1,800ft. of Pipes for rain-water drains.
Messrs. Sharp, Jones and Co. (Parkstone, Dorset) (Second Gift).—Sixteen complete rock concrete Manholes.
The Rugby Portland Cement Co. (Rugby) (preliminary).—One Truck-load Portland Cement.
Messrs. Stanley Bros. (Nuneaton).—250 Yards of Tile Flooring for one Home.
Messrs. R. H. and J. Pearson.—Four complete Grates, with mantels, overmantels and hearths.
Messrs. E. W. Payne and Co. (Staple Hill, near Bristol).—50 cubic feet Pennant Stone for door-cills.
Messrs. G. S. S. Williams and Son.—The Staircase for one Home.
Messrs. Ashton and Green Iron Co.—Stoves and Ranges for one Home.
The Cyanite Paint Co.—"Fireproof" Paints for Recreation Hall, Engine House and Kitchens.
Mr. John Bellamy.—A Galvanised Iron Cistern and a Hot-water Tank.
Mr. J. M. Boekbinder.—Plaster Decoration for the Recreation House.
Messrs. Pilkington and Co.—Asphalt Paving under floors throughout buildings.
Messrs. Engert and Rolfe.—Bituminous Felt for the Recreation House.
Messrs. Francis and Co.—10 tons Portland Cement.
Messrs. Joseph Cliff and Son (Wortley, Leeds).—The complete Sanitary Ware for two Homes.
The Camoo Wood-Working Co. (Loughborough, Leicestershire).—1,000ft. of Mouldings.
Messrs. Noyes and Co.—2,500 Wall Ties.
The Coalbrookdale Co.—One Iron Staircase.

VARIOUS GIFTS FOR THE EQUIPMENT OF THE HOMES.

Messrs. J. S. Waring and Sons.—The entire Furniture for one Home.
Messrs. Wilson and Stockall (Lancashire).—One Hand-wheeled Litter Ambulance.
The Berkefeld Filter Co.—Five Filters.
Messrs. Williams and Co. (Hackney).—One Washing Machine for Laundry.

Legal Position of Architects in relation to Local Authorities.

By E. J. NALDRETT,
BARRISTER-AT-LAW.

A MEETING of the Society of Architects was held on Thursday evening last at St. James's Hall, Piccadilly, W., when Mr. Silvanus Trevail, F.R.I.B.A., J.P. (vice-president), presided. After Messrs. M. Hall (Halifax) and W. Stair (London) had been elected members, and Mr. G. E. Mitchell (Lowestoft) had been elected student, the following paper on "The Legal Position of Architects in relation to Local Authorities" was read by Mr. E. J. Naldrett, Barrister-at-Law:

This paper deals with the circumstances under which an architect may, sometimes, be called upon to carry on his work. The legislature has, within the last twelve years, not only brought new authorities into existence, but has largely extended the powers and duties of those which have been from time to time constituted. The Local Government Acts of 1888 and 1894 are landmarks in the history of local government outside the metropolis, and most important changes in the constitution of governing bodies within the metropolis are introduced by the London Government Act, 1899. Under our present system, we have county and district councils, municipal corporations, school boards, boards of guardians, and other bodies. These authorities are alike in this respect, that they are all corporate bodies having perpetual succession and a common seal, and consequently are within the general rule of law which requires the contract of a corporation to be under seal, subject to certain exceptions, which will be noticed presently.

A local authority may, and there are not wanting instances in which this has been done, appoint an architect as their permanent officer. This renders it necessary to consider the powers of the various authorities relative to the appointment of officers. An authority may retain the services of an architect without constituting him their permanent officer. This is the course generally adopted. In both cases the relation is contractual, but in the first-named regard must be had to any special provisions which may exist as to the appointment of officers, as well as to the formation of contracts. It is of the utmost importance to architects that the circumstances under which a valid and binding contract may be entered into with a local authority should be fully appreciated. It is probably within your knowledge, if not within your experience, that many a fee has been lost in consequence of some defect in the form, or in the mode of execution, of a contract with a local authority. Claims, just and reasonable in themselves, have been defeated by insistence upon some such technical objection on the part of the authority. I cannot do better, in drawing your attention to the general rule of law as to the

Contracts of a Corporate Body,

than refer to the case of *Church v. Imperial Gas, &c., Co.* (6 A. and E., 861), decided as long ago as 1838, in which Lord Denman, C. J., said: "The general rule of law is that a corporation contracts under its common seal: as a general rule, it is only in that way that a corporation can express its will or do any act. That general rule, however, has from the earliest traceable periods been subject to exceptions, the decisions as to which furnish the principle on which they have been established, and are instances illustrating its application, but are not to be taken as so prescribing, in terms, the exact limit, that a merely circumstantial difference is to exclude from the exception. The principle appears to be convenience amounting almost to necessity. Wherever to hold the rule applicable would occasion very great inconvenience, or tend to defeat the very object for which the corporation was created, the exception has prevailed: hence the retainer by parole of an inferior

servant, the doing of acts very frequently recurring, or too insignificant to be worth the trouble of affixing the common seal, are established exceptions." The principle thus laid down has been confirmed and followed in subsequent decisions. When a board of guardians appointed a clerk to the master of a workhouse, not by deed (that is, not under seal), and during his tenure of office discharged him, it was held that an action for wrongful dismissal would not lie as the appointment was not under seal. In another case it was laid down that the making of plans for offices was not of frequent occurrence nor a necessary part of an urban authority's business. It is quite clear, therefore, that the appointment of an architect is not an event of so frequent occurrence or of so small importance as to take it out of the operation of this general rule of law, which requires that the contract should be under seal. This general rule, applicable to corporate bodies, must be considered in connection with the statutory provisions regulating the proceedings of the various local authorities. I think it will be convenient if I now pass to a consideration of some of these special provisions concerning the appointment of officers and the formation of contracts.

Education Act, 1870

(32 and 33 Vict., c. 75). This Act, in section 35, provides that a school board may appoint "a clerk, a treasurer and other necessary officers" to hold office during the pleasure of the board. The authorities may assign to their officers such duties and salaries or remuneration as they think fit, and may from time to time remove them from office. No such appointment is to be made, except at a first meeting of a school board, unless notice in writing has been sent to every member of the board. Two or more school boards may arrange for the appointment of the same person to be officer to both or all of such boards. Schedule III., rule 7, of the Act provides that the appointment of any officer may be made by a minute of the board, signed by the chairman and countersigned by the clerk (if any), and any appointment so made shall be as valid as if it were made under the seal of the board. In this provision we have a statutory exception to the general rule of law. The appointments of school board officers are not liable to stamp duty. There are no special provisions as to other school board contracts in the Education Acts. The general rule of law applies to them. The following decisions of the courts are very instructive as to the relations which may exist between school boards and architects whose services they retain.

In *Scott v. The Clifton School Board* (14, Q.B.D. 500) the plaintiff by a minute, signed by the chairman and countersigned by the clerk, was appointed architect of the board, and under orders given by subsequent minutes, so signed and countersigned and communicated to him, he prepared plans for the board. It was held that, by virtue of the provisions of the Act, he was entitled to recover payment for his services, although the appointment and orders were not under seal. It will be seen by the judgment of Mr. Justice Mathew in this case that, owing to the nature of the appointment, the architect became an officer of the school board.

In *Start v. West Mersey School Board* (15 T.L.R., 442) Mr. Justice Wills, in giving judgment, said that the claim of the plaintiff took the form of an action for services rendered. The only real contract between the parties was one expressed in a resolution by the defendant corporation to pay the plaintiff $\frac{1}{2}$ per cent. on the cost of construction of the buildings to be erected. The action was in substance an action for breach of that contract, which was not under seal. He would have been glad if he could have taken a different view of the case, for the objection that the contract was not under seal was not one with which he could have sympathy. The objection had been taken, and he could not alter the law. Judgment was given for the defendants, with costs.

In the first case the plaintiff, an architect

became an officer of the school board, and, owing to the special provisions of the Act, he was able to recover for his services rendered, a contract under seal not being necessary. In the second case the plaintiff was not an officer of the board, and relied on a contract for services rendered. He failed to recover because the contract was not under seal.

In another case a school board resisted a claim by an architect for £250 as damages for breach of contract to employ him in the erection of schools, and for the loss of 5 per cent. on the cost of the buildings, on the ground that the resolution purporting to appoint the architect was not signed by the chairman and countersigned by the clerk as required by the rule, and was not under seal. The case was settled by judgment being entered for the defendants, without costs, the unfortunate architect receiving only £10 10s., which had been paid into court. I will now pass to the provisions of the

Public Health Act, 1875

(38 and 39 Vic., c. 55), which imposes upon an urban authority the duty of appointing a clerk, a surveyor, and certain other officers, also, "to appoint or employ such assistants and other officers . . . as may be necessary and proper for the efficient execution of this Act" (section 189). The authority may make regulations as to the duties of officers, pay them reasonable salaries and allowances and remove them at their pleasure. The Act also contains provisions that officers are not to be concerned or interested in any bargain or contract with the authority for the purposes of the Act, prohibiting the acceptance of any fee or reward other than the proper salary and allowances, and as to security being given in certain cases. A surveyor is a recognised officer, but an architect is not mentioned in the Act. The words "and other officers" are probably wide enough to cover the appointment of an architect as an officer of the authority. In such a case the foregoing provisions, as to the appointment of officers, would apply to him. This course is not likely to be adopted to any extent for several reasons; one is, that the surveyor is often called upon to discharge the functions of an architect in connection with small undertakings; and another is, that it is always open to the authority to retain the services of an architect, when required, by contract in the ordinary way.

The Public Health Act, 1875, contains provisions as to contracts by an urban authority to which I invite your attention. Every contract, the value or amount of which exceeds £50, must be in writing and sealed with the common seal of the authority. It must specify the work, materials, matters or things to be furnished, had or done, the price to be paid, and the time or times within which the contract is to be performed; also, it must specify some pecuniary penalty to be paid in case the terms of the contract are not duly performed. These provisions contained in sub-sections 1 and 2 of section 174 are obligatory, not directory merely, and unless observed the contract cannot be enforced. The following sub-sections, 3 and 4, contain directions to be observed by the urban authority, but they are directory only, and a failure to comply with them, on the part of the authority, would not render inoperative a contract in other respects valid. There are a number of decisions by the courts on cases arising under this section. I will refer to some of them by way of illustration. The defendants, an urban authority, verbally directed their surveyor to employ the plaintiff, an architect, to prepare plans for offices. The plans were prepared and the defendants advertised for tenders for building the offices in accordance therewith; but when these were sent in it was found that the plaintiff's plans were upon too expensive a scale, and the intended offices were not erected. There was no ratification under seal of the Act of the act of the plaintiff's surveyor in procuring the plans. At the trial the jury found that offices were necessary for the purposes of the defendants, and the plans were necessary for the erection of the buildings for which they were designed, and that the cost of the plans

was £94. It was held that, assuming the contract was founded on an executed consideration, the plaintiff could not recover, for section 174 was imperative and not directory, and applied to every contract for a sum exceeding £50 entered into by an urban authority (*Hunt v. Wimbledon Local Board, L.R., 4 C.P.D. 56*). It has also been held, following the case I have cited, that sub-section 1 applies to an executed contract of which the urban authority have had the full benefit and enjoyment, and which has been effected by their agent, duly appointed, under their common seal. An urban authority by contract, not under seal, employed an engineer to perform certain work exceeding in value £50; this he did, and then required the authority to affix their seal to the contract. This they did. It was held that as part of the work was unperformed when the seal was affixed, and there was consideration for affixing it, in the engineer's promise to complete the work, it was competent for the authority to constitute the contract a good contract, under seal, within section 174, in respect of the work already done, and that therefore the engineer was entitled to maintain his action for the value of that work. The absence of a contract under seal is not the only objection which has been successfully taken. A company entered into a contract with an urban district council in writing, duly sealed by the authority, to light by means of electricity certain streets, for a period of five years, for an agreed annual payment. The contract contained stipulations with respect to the materials to be supplied, the things to be done, the prices to be paid, &c., but contained no clause specifying any pecuniary penalty to be paid in case its terms were not duly performed. It was held that the contract could not therefore be enforced against the authority. We have it upon the authority of a very eminent judge that the provisions of the sub-sections 3 and 4, to which I have referred, are directory only. A similar duty to appoint officers is imposed by the Act upon rural district councils. The provisions as to contracts relate to urban councils only. They apply to a municipal corporation when acting as an urban sanitary authority.

Municipal Corporations' Act, 1882

(45 and 46 Vict., c. 50). In this Act also are provisions for the appointment of certain officers, followed by the general provision that a council shall from time to time appoint "such other officers as have been usually appointed in the borough, or, as the council think necessary," with reasonable remuneration, and to take security for the due execution of the office. It is improbable that an architect would be appointed an officer of a municipal corporation except in so far as the borough surveyor may discharge the functions of an architect. Municipal corporations, however, frequently retain the services of an architect, and the ordinary law as to contracts by corporations, which I have described, governs the relations. The contract should be in writing and under seal. There are no special provisions such as are to be found in the Public Health Act, 1875, but a municipal corporation, when acting as an urban sanitary authority, must follow the requirements of the last-named Act.

Local Government Act, 1888

51 and 52 Vict., c. 41). A county council has under this Act the power to appoint, to remove, and to determine the salary of a county surveyor. There are provisions for protecting the interests of existing officers at the time of the passing of the Act. The powers of a municipal corporation to appoint officers, other than those specifically named, are conferred upon county councils, together with the right to require security and to determine the remuneration, &c. A county council being a body corporate must contract in accordance with the general rule of law. It was under this Act that the officers of the Metropolitan Board of Works became the officers of the London County Council, and the powers, duties, and liabilities of the former body were transferred to the

latter. The powers of the superseded authority, in relation to officers and contracts, are noticed in the reference to the Metropolis Management Act, 1855.

London Government Act, 1899

62 and 63 Vict., c. 14). Under the provisions of this statute the vestries and district boards of the metropolis will be superseded by the establishment of borough councils. The powers and duties are transferred. The Act protects the interests of existing officers by providing compensation for those whose offices are abolished, or who suffer pecuniary loss. A reference must be made to the Metropolis Management Act, 1855, for the powers of the new councils as to the appointment of officers and entering into contracts. It will be their duty to appoint or continue, with power to remove at pleasure, certain officers, named in section 62, and "such other officers" as may be necessary for the purposes of the Act. There are provisions as to remuneration, taking security, &c. The councils will have power to enter into all such contracts as they may think necessary for carrying the Act into execution. Every such contract for works or materials the value of which exceeds £10 is to be in writing, and sealed with the seal of the authority. Copies of contracts are to be entered in books kept for the purpose. It may be pointed out that under the London Building Act, 1894, the London County Council may appoint a superintending architect of metropolitan buildings, with power to remove him and to prescribe the duties and salary to be attached to the office. An architect so appointed is prohibited from practicing or following any other occupation. He may, however, if he should be prevented by illness, infirmity, or other unavoidable cause, from attending to his duties, temporarily appoint a deputy with the consent of the council. The district surveyors of the metropolis are also under the control of the London County Council, and as vacancies occur they may appoint qualified persons to fill them.

Poor Law Acts

4 and 5 Wm. IV., c. 76, &c.) The Poor Law Acts and orders contain very precise provisions as to certain appointments enumerated, but there appears to be no general provision under which an architect can become an officer of a board of guardians. The ordinary contractual powers of a corporate body must be exercised by guardians when retaining the services of an architect. Contracts by guardians must conform to the rules of the Local Government Board. These regulations are applicable to contracts for the supply of goods and the execution of works, rather than to the engagement of professional services. The contract should generally be under seal and relate to some matter incident to the duties of guardians. Services retained by minute might be legally paid for by the guardians, but an architect, in the absence of a contract under seal, would not be in a position to recover for his services, except, possibly, in cases where a small amount becomes payable in connection with some obviously necessary proceeding. There are many judicial decisions on cases of

Contracts not Under Seal

in which guardians have been concerned. I will give a few examples in order of date. A contract for making a plan, not incident to purposes for which guardians are incorporated, is not binding. Gates erected at a workhouse, ordered verbally, are necessities and the guardians are liable to pay the price. A builder who executes works in addition to those specified in a sealed contract cannot recover the value. A tradesman who erects water-closets at a workhouse can recover the cost as the purposes for which guardians are incorporated require that they should be provided. A collector of poor rates cannot recover his poundage. A person employed to investigate incorrect union accounts is entitled to recover for work and labour done. These are all cases of a contract not under seal. You will not fail to realise the importance, in your relations with boards of guardians, of having a contract under seal.

There is one other matter I desire to draw your attention to in connection with guardians. The time for the payment of their debts, &c., is limited to the half-year within which they have been incurred or become due, or within three months after the expiration of such half-year, unless the Local Government Board extend the time, which they may do, for a period not exceeding twelve months after the date of the debt, &c. The half-years end on March 25th and September 29th. A parish council is a body corporate, but it need not have a common seal. Any act of the council may be signified by an instrument executed at a meeting of the council, and under the hands, or if an instrument under seal is required, under the hands and seals of the chairman presiding at the meeting, and two other members of the council. I have now dealt with the special provisions of the more important of the Local Government statutes. I have not attempted to deal with the provisions of local Acts. It remains for me to make a few

General Observations.

The appointment of an officer by a local authority appears to be complete by election, and no document in writing is required, but there should be a minute. The authority may properly pay the agreed salary or remuneration in respect of such an appointment. If, however, the officer seek to raise any question as to a breach of the engagement, in a civil court, the proceeding will fail if the contract be not under seal. This last observation does not apply in the case of a school board, to an appointment under the Public Health Act, if it be worth not more than £50, and under the Metropolis Management Act, 1855, if it be not more than £10 in value. Notwithstanding conflicting decisions upon the point, the same principle seems to apply to payments by an authority on an apparent contract, apart from the appointment of officers, not strictly in accordance with the provisions of the statute. For example, a contract under the Public Health Act exceeding £50 in value and not under seal. When the debt is justly incurred there is nothing illegal on the part of the authority in meeting it, although the payment is one which could not be enforced by the other party to the contract. I am, perhaps, in danger of travelling outside the subject in asking you to note that when an urban authority enter into a contract in writing and under seal with a contractor for the construction by him, e.g., of sewerage works, and the contract contains the usual power for the engineer, who has the control and supervision of the works, to vary, alter, enlarge, or diminish any of them, all variations and alterations coming within the terms of the power conferred on the engineer can be validly made without being under the seal of the authority. The fact must be borne in mind that the statutory authorities referred to cannot travel outside the powers conferred on them by statute. Their acts would be *ultra vires*. Obligations entered into by authorities in the most solemn form, are not binding upon them, if *ultra vires*.

There is another statute to which I feel it is important to draw your attention, viz., the

Public Authorities Protection Act, 1893

(56 & 57 Vic., c. 61). It contains the provision that where any action, prosecution, or other proceeding is commenced in the United Kingdom against any person for any act done in pursuance, or execution, or intended execution, of any Act of Parliament, or of any public duty or authority, or in respect of any alleged neglect or default in the execution of any such Act, duty or authority, certain provisions are to have effect. One of them is, that the action, prosecution, or proceeding shall not lie or be instituted unless it is commenced within six months next after the Act, neglect or default complained of, or, in case of continuance of injury or damage, within six months next after the ceasing thereof. It has not been determined by the Courts whether this provision applies to a debt due from a local authority. My suggestion to you is that delays are dangerous. If you should

be so unfortunate in your relations with a local authority as to find a resort to legal proceedings necessary, see that you move within the prescribed limit of six months, and so avoid the unpleasant experience of discovering that a short lapse of time can be an effectual bar to your claim, and that you have become liable to pay solicitor and client costs.

It has been suggested that this paper would not be complete without a reference to the subject of competitive designs. It is the practice of local authorities to invite architects to send them designs under conditions favourable to themselves, but not always quite satisfactory from the point of view of the architect. I have before me one of these formal invitations which may probably be taken as a fair example of this kind of document. Its terms are such that the local authority reserve to themselves an almost entirely free hand. The acceptance of a design is hedged about with qualifications. If accepted there is no obligation upon the authority to carry out the works in accordance with it. Even if the authority accept and carry out a design they are free to appoint an architect, other than the author, to supervise the works. The estimated cost upon the designs are based is open to amendment. In these circumstances, beyond securing a premium for an accepted design, an architect has no claim upon the authority, however much of skill and care he has bestowed upon the preparation of the design submitted. He voluntarily places himself in the hands of the authority. In most instances he may safely do this and rely upon being honourably and fairly treated by the authority. I am informed that exceptions occur and a grievance is sometimes felt. There is no legal remedy.—A discussion followed, in which Messrs. Silvanus Trevail, W. R. Mallett, J. W. Dunford, and Ellis Marsland took part.

Correspondence.

Ellipse by Compasses.

To the Editor of THE BUILDERS' JOURNAL.

WALTON-ON-THAMES.

SIR,—Will Mr. J. A. Percival and Mr. R. E. Marsden please refer to the supplement to the article of December 6th, given on page 52 of the present issue, and consider Fig. 15 as a reply to their letters in your issue of January 3rd last. In the same issue, "Student" asked a question as to the drawing of an ellipse. This was replied to by Professor H. Adams, and finished thus: "Compass curves are all circular and cannot, therefore, be parts of an ellipse, which is a curve of constantly varying radius." The latter portion of the additional matter I send is partly in answer to this reply to "Student." R. RAMM.

[Mr. Ramm informs us that illness has prevented him replying earlier.—Ed. B.J.]

A Doomed Church.

To the Editor of THE BUILDERS' JOURNAL.

EXETER.

SIR,—In your issue for February 14th, is an illustration of All Saints' Church, Lambeth, S.E., which we learn will shortly disappear, with the rest of the parish, to make way for the extensions connected with the London and South-Western Railway terminus at Waterloo. To the report is added: "Never before has a whole parish been wiped out for railway purposes." The present wholesale demolition, however, cannot really boast of such a distinction. When St. Pancras Station was built, certainly one whole parish, if not two or three, were entirely cleared away, as well as an excellent church with a pleasant spire (for a London spire), that used to stand upon the north side of the New Road, now known as Euston Road. The church and adjacent terrace were recessed from the actual roadway, and divided from it by bright green and well-kept grass, the swarded enclosure being protected by low posts connected by loosely-hung and spiked chains. But in spite of the

spikes—fifty years ago—I have enjoyed many a happy swing upon those self-same chains.—Yours obediently, HARRY HEMS.

RICHMOND.

SIR,—Mr. Hems is in error when he states that "one whole parish, if not two or three, were entirely cleared away" for the building of St. Pancras Station. The church and graveyard were destroyed, but this does not imply the entire sweeping away of a "parish." As a matter of fact the neighbouring Wharf Road, Battle Bridge Road, Ossulston, Phoenix, and Bull Streets to the north and west, and the many mean streets giving off York Road remain as fragments of the parishes largely, but not by any means wholly, acquired. I am sorry to have to correct Mr. Hems, whose foible appears to be omniscience.—Yours faithfully, C. G. H.

Valuation of Houses (Repairs and Empties).

To the Editor of THE BUILDERS' JOURNAL.

LONDON, S.E.

SIR,—If there is one thing more than another that vexes the soul of the owner of house property, it is the burden of repairs and "empties," the sting of which vexation lies in a disappointment. His agent or surveyor had made out a nice little statement showing rent, deductions, years' purchase, and total value—a rosy picture—and he eagerly purchased, only to be bitterly disillusioned when the ugly facts of losses and expenses came home. It is more difficult to justify than it is to understand why the average house-agent fails to muster up enough moral courage to tell his clients the plain truth on these matters. It must be the optimism characteristic of the profession that leads a valuation surveyor to dwell on the memory of some fortunate property, and to forget all others, when they coolly set down 10 per cent for repairs, and 5 per cent for empties and losses, and so succeed in effecting a sale. These thoughts beset me when I read on page 26 of the BUILDERS' JOURNAL for February 14th how that your expert, Mr. Brand, P.A.S.I., has the courage to go even one better than this, and to give us 5 per cent for repairs, and 2½ per cent for empties and bad debts. Such a figure is seen to be inadequate and misleading, when one remembers that a house needs redecoration in its various parts every three to ten years respectively—say equal to once throughout every seven years. Such a "through-out" seldom costs less than one year's rent—often much more. There, then, at once, is 14 per cent, to which must be added the necessary current repairs to ranges, roofs, drainage, plumbers' work, &c. This would be "repairs" under favourable circumstances. But what of some other, all too common, dangers to the pocket, i.e., when the drainage has to be reconstructed, when ugly cracks appear in the walls and ceilings, and the tenants refuse any longer to put up with the inconvenience arising from dry rot, smoky flues, damp walls, and other fundamental defects. Then again, the luxuries of the past have become the necessities of the present, and many an unfortunate owner is troubled with a pretentious old house lying fallow for lack of modern "appointments," and he finds himself compelled, at last, to spend, perhaps, half its value, or more, in improvements to make it "go." I could give hundreds of illustrations of this from my own practice. I will give some details of one which happens to be before me at the moment. It is a house in St. George's Road, Pimlico, gross rental value £120 per annum; built, I should say, about forty-five years ago; present owner bought it ten years ago, apparently in good order. In 1896 it was redrained at a cost of £70. Last autumn competitive estimates were obtained for general repairs and quite plain decoration, for which £477 has now to be paid. This sum included no improvements, and as the house is used as a charitable institution, not a farthing has been spent beyond bare necessities. Now, this ought to last for the next fifteen years, with, say, twice redecoration—at £90 each—and at least £5 a year for small current repairs. On

the total term of twenty-five years of ownership, this will show a total expenditure for repairs of £800, or 28 per cent. per annum on the rental value.

I cannot, just now, refer your readers to any published accounts of the class of leasehold property instanced by your expert, but if he or any other member of the Surveyors' Institution will turn to the "Transactions" of that body, vol. XXVI., p. 304, he will see a number of property accounts, including nine groups of small leasehold property in which the average over the whole, for repairs only, is about 25 per cent, and for empties 7 per cent. It is easy to produce a house that has cost almost nothing for repairs within a limited period, but sooner or later the expense must come, and the true annual value of repairs can only be ascertained over a long term. I should be glad to hear from any house-agent that the cost of one residence or a group has, over a term of say twenty-five years, not exceeded 12 per cent per annum; if it has not—and it is quite possible in isolated cases—whether the average of his whole business comes below that percentage as shown by, and worked out from, actual accounts, adding, of course, any sums paid for repairs by the client direct to his builder and not shown in the house-agent's books.

Turning now to empties and bad debts, Mr. Brand gives it to us as 2½ per cent,—a joy to contemplate if it were true; but it is sadly underrated and can only be taken as a minimum, not as an average. This risk varies in actual fact from 2½ per cent. to 100 per cent. It is a very speculative item in dealing with one house, and can only be approximated by taking the risk as it shows itself in a large number of houses. I should myself have set it down at from 5 per cent. to 12 per cent. or more, according to my knowledge of the property and the locality. The most favourable tenancy that one could expect would be one bearing a loss of only one quarter in fourteen years, namely, 2 per cent. But what of those houses that are frequently empty, of restless or dissatisfied tenants, of declining neighbourhoods, etc.; and what of tenants that get hopelessly in arrears? Your readers must know of many properties that have been long empty, and a very little of that sort of thing soon brings up the percentage. No house should be considered free from such risks. Let any house-agent refer to his books and compare his nominal total rent roll with the cash actually received; one need not wonder how many will come up to Mr. Brand's 98 per cent., or even how many will amount to 90 per cent.

Finally, what does your expert mean by his statement: "It is not usual to deduct property tax or Schedule A income tax, for the reason that all kinds of property, landed or otherwise, are chargeable; but all other taxes paid by the owner, in addition to . . . land tax (if unredeemed), tithe, water rate, etc. . . . must be deducted"? And what are the "rates and taxes" referred to as £5 in the example given?—Yours faithfully,

F. S. I.

The Somerset Arts and Crafts Association has decided to postpone its exhibition till the spring of 1901.

Excavations at Jerusalem.—An important part of the excavations which have recently been carried on by Dr. F. J. Bliss at Jerusalem was the clearing of the famous Pool of Siloam, which to this day is used by the Arabs as a bathing place. Search was also made for the tomb of David, and at one time Dr. Bliss was of opinion that he had succeeded in finding it, but further digging contradicted this view.

FIVE SHILLINGS IS THE PRICE of the last issue of "Specification," the valuable reference book for architects and builders. It is cheap at the price, but you can get it for nothing by complying with the simple conditions mentioned on page 56.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"Build by whatever plan Caprice decrees,
With what materials, on what ground you
please."—COWPER.

Our Inset Plates.

THE house at Hampstead is to be erected on a site in West Heath Road overlooking the Heath, and the rooms are planned round a square hall, which is carried up above the roofs to form a smoking room, from which extensive views will be obtained of the surrounding country. The building will be faced with red bricks and stone dressings, the upper floor being stuccoed, the gables half-timbered, and the roofs covered with green slates. The hall will be furnished with high wainscot dado, ornamental plaster friezes and scagliola piers. The architects are Messrs. Harrington and Ley, of 108 Fenchurch Street, E.C. The Galilee porch of Ely Cathedral is a very fine example of early English design and is often considered to have no equal—except perhaps that of Durham. It was built by Eustace, Bishop of Ely (A.D. 1198—1215) at his own cost. The reproductions we publish are from the measured drawings of Mr. Charles E. Varndall. The sketch of Duart Castle is by Mr. F. Inigo Thomas.

Strand Improve- ment.

AMONG the many more or less interesting and picturesque buildings which will be destroyed in connection with the Strand improvement is the famous old tavern, the "Spotted Dog" in Holywell Street. The sign of this house consists of a white dog with black spots, so fashionable some years ago. Half a century back the house was kept by one "Spotty Wilson," and at that time was in close connection with another further west, known as the "Bull's Head." Both the "Spotted Dog" and the "Bull's Head" were in their time well-known meeting places for those interested in prize-fighting; it was at the latter place that all the arrangements were made in relation to the great fight between Tom Sayers and Heenan, the American, in 1860. In connection with the impending destruction of Holywell Street, it will be interesting to refer to our article and illustrations published in No. CCLIV.

Church Crafts League.

THE inaugural meeting of the Church Crafts League was held at Leighton House on February 20th. The Bishop of Rochester was elected president, and Dr. F. D. Drewitt honorary treasurer. The following artists were elected to serve on the committee:—Sir W. B. Richmond, R.A., Mr. Henry Holiday, Mr. W. Goscombe John, A.R.A., Mr. Conrad Dressler, Mr. A. G. Walker, Miss Emily Ford, Miss Lowndes, Mr. T. Stirling Lee, Mr. Alex. Fisher, Mr. Byam Shaw, Mr. C. O. Skilbeck, Mr. J. Phillips. Also the following clergy and others:—Canon Rhodes Bristow, Canon Henry Scott Holland, Canon Gore, Canon Armitage Robinson, Rev. Charles Biggs, Rev. Percy Dearmer, Hon. Mabel de Grey, Mrs. Russell Barrington, Mr. Dyer Edwards. The rules and objects drafted by the provisional committee were then discussed and adopted, the objects being—(1) To bring the clergy and others responsible for the construction and decoration of churches into direct relation with artists and craftsmen engaged upon work of the kind; (2) by this means to restore individual character to art in churches, and to remedy the evil results of commercialism in the matter. The members of the league will be either "ordinary" or "artist" members, and the latter class will be elected by a two-thirds majority of artist members present at a meeting after due notice given. The committee is to consist of twenty-four members besides the president and treasurer, of whom twelve are to be artists, and not less than six clergy. It was announced that the following had consented to be patrons of the league:—Mr. G. F. Watts, R.A., the Archbishop of York, and the Bishops of Bristol and Steyney. The temporary address is: The

Secretary, Church Crafts League, Leighton House, 2, Holland Park Road, Kensington, W.

Discoveries at Furness Abbey.

THE researches which Mr. St. John Hope has been making at Furness Abbey on behalf of the Cumberland and Westmorland Antiquarian Society have shown that there have been several rebuildings of the church; the transepts have been lengthened, and the chapel has had apsidal ends; and so has the presbytery, so far as the evidence goes, for the second builder there destroyed the work of the first, and the third destroyed the work of the second with a recklessness worthy of a nineteenth-century restoring architect. Where graves came in their way they took up the bones and flung them into a heap in a hole dug just east of their new works. But most important of all, Mr. Hope has been able to work out the plan of Furness, when it was Savignian, before it became Cistercian. The successive enlargements of the cloisters, from a square shape originally, have been proved. Mr. J. F. Curwen, of Kendal, has undertaken, at the suggestion of the president of the Antiquarian Society (Chancellor Ferguson, of Carlisle), to make a careful plan of the curious way in which, in the presbytery, the fifteenth-century builders superimposed their work on that of the twelfth-century builders. The excavations which have been made have been a great drag on the Society's funds, but have been well worth the outlay.

Forum Excavations.

THE Church of S. Maria Libera-trice (says the Rome correspondent to the "Globe") is now no more, and the vast north-west angle of the Palatine, gloomy with the ruins of Caligula's palace and the dark grove of Ilex above them, may be almost said to frown over the Forum; for the cloudy skies, for which the present year has been so remarkable, still prevail. The late edifice, built in 1550, and restored by Cardinal Lante in 1617, must have been again restored in the earliest part of this century, although the fact has not been noticed by Nibby or other antiquaries, for under the base of one of its piers were found coins of Pius VII. The handsome "Africano" pavement of the Basilica Emilia promises to become one of the attractions of the Forum. More and more of it is coming to light. Having, however, revealed suspicious breaks in its continuity at certain symmetrical points, Signor Boni has opened the ground with the profitable result of discovering the cavities made for the former columns of the central hall, or nave. This is a matter of considerable importance, for two reasons. Firstly, it enables one to perceive that the Basilica, like that of Trajan, was constructed in "cinque navate," or five naves; and, secondly, it permits us to calculate the actual width of the great building, although, until another £2,500 may be forthcoming, it will not be possible to clear the entire site and see the northern colonnades. At various points are seen (literally) clots of bronze money much oxidised, which have been dropped therein by money-changers, probably in their flight during earthquake or fire, resulting in the collapse of the building.

The Sacred Way.

WHILE referring to these Forum excavations, an extract may be given from a letter in the "Times" by Professor Rodolfo Lanciani, whom the Royal Institute of British Architects have this year proposed as the recipient of the Royal Gold Medal. In reply to a statement of Professor Richard Norton, director of the American School of Classic Studies in Rome, he says: "In my last volume on the 'Ruins and Excavations of Ancient Rome,' pp. 181 and 206, I have distinctly stated that the course of the Sacred Way underwent at least three changes in Imperial times, the first after the fire of Nero, A.D. 65, the second after the fire of Commodus, A.D. 191, the last after the fire of Carinus, A.D. 283. This noble avenue, this Sacred Way of the late empire (its name was certainly not changed by Maxentius), this witness of the last three centuries of Roman life, measured

23 metres across from building to building, and 12'35 metres between the side-walks. The one running along the Porticus Margaritaria is 8'20 metres wide, and encumbered by many monuments, such as fountains, hemicycles, excubitoria, &c.—all post-Maxentian—mixed up with older relics (altars, pedestals, shrines), which must have been raised to the new level. This most beautiful specimen of the architectural and engineering skill of the third century is no more, if we except a short section in front of the Heroon Romuli, which is also destined to disappear. It has been obliterated to lay bare the Sacred Way and its surroundings of an earlier date."

The Founders' Competitions.

THE Master, Wardens and Court of Assistants of the Worshipful Company of Founders will hold at Ironmongers' Hall on May 9th and 10th an exhibition of designs and models in metal, wood, plaster, or any suitable material for casting, and will give a number of prizes to be competed for by founders, designers, craftsmen, and apprentices engaged in foundry business or allied trades within the City of London, or the area of the metropolitan police. Among the prizes offered is a special one of £10, given by the Worshipful Company of Ironmongers, for First Class (C) for the best panel in ornamental figure. In regard to the prizes given by the Founders' Company, it is intimated that the freedom of the company may be given in cases of special merit. The money prizes are divided into three classes—first, second (for apprentices only), and third (improvers under the age of twenty-five). Each of these classes is subdivided as follows:—(A) for the best casting (any subject); (B) for the best group, or figure, or head; (C) for the best panel in ornamental figure; (D) for the best bell (not to exceed 9in. in diameter); (E) for the best design, which may be a drawing, model, or pattern, for any kind of cast metal work. Applications are to be made to the clerk of the Founders' Company, at Founders' Hall, St. Swithin's Lane, E.C., and the works are to be delivered at Ironmongers' Hall on May 8th.

Artistic Copyright.

MR. EDWIN BALE dealt with this subject at last Wednesday's meeting of the Society of Arts, when Sir L. Alma-Tadema presided. Mr. Bale sketched the history of artistic copyright, and commented on the law under the existing Act. After promising the author copyright in his work for his life and seven years, the Act went on to say that in order to get that, when he first sells or disposes of his picture he must say to the intending purchaser: "There are two properties in this work—the picture and the copyright; I am only selling you the picture, and must ask you to sign a document reserving the copyright to me." And if the artist did not take this step and get this document, the Act gave the copyright to the purchaser of the picture; but, again, also "provided," and this time the purchaser got his cold douche, for in order that he might have the copyright he must have a document, signed by the artist, reserving the copyright to him, and if neither of these things were done, and no document were signed, the copyright did not belong to either the artist or the client. It had disappeared, and belonged to no one; there was no copyright existing in the work for anyone. He also explained the remedies proposed in the new Bill, of which the main features were: (1) To secure greater uniformity in the terms and conditions of copyright; (2) to reserve to the artist, with certain exceptions, the copyright until expressly assigned or disposed of by him; (3) to make registration of copyright, with certain exceptions, and of all dealings therewith compulsory; (4) to improve the remedies for infringement. There were two terms of copyright conferred by the Bill—for an original work of fine art, the life of the author, and thirty years after his death; and for a work of fine art made by one person from the design of another, for a photograph, for a cast from nature, thirty years from the first day of the month of registration.

Professional Practice.

Barry.—The new Board School which has been erected in Hannah Street has cost £13,400 and accommodates 1,300 scholars, exclusive of the manual instruction school. Messrs. J. P. Jones, Richards and Budgen, of Cardiff, were the architects, and Mr. Allan Richards was the contractor. The main building fronts Barry Road, and the elevation is carried out in brick with Bath stone dressings, one of the best features being the central halls, which are 60ft. long by 26ft. wide. No classroom has accommodation for more than sixty scholars. Open fireplaces are not used, the rooms being heated in the same manner as those at Clive Road Schools, Barry Island, by means of hot air forced by a rotary fan worked by a gas engine at the base of the building. Ventilation is provided on the Musgrave-Plenum system, while in the summer the air can be cooled before passing into the rooms. A novel feature is the provision of blackboard dado around the rooms and halls for demonstrative purposes. Provision is also made for the systematic teaching of general elementary science in a thorough and practical manner.

Birmingham.—The Midland Arcade, of which an illustration is here given, is being carried out by arrangement with "The

City Arcades" and is, in fact, a branch of that building. A large portion of one side will be occupied by "The Louvre," and the arcade will run through from High Street. There are in addition, fourteen shops, three of them, as shown, fronting to New Street. The interior decoration will be carried out in slab mosaic of brilliant colouring. The frontage to New Street will be of buff terracotta and narrow bright red bricks. The fascias to the shops will be modelled in fibrous plaster. This building, together with the City Arcades, is being carried out from designs by Messrs. T. W. T. Newton and Cheate, of 33, Newhall Street, Birmingham. The total cost of the whole arcade schemes, in the centre of Birmingham, will be nearly £200,000, and the ground rents are about £7,000 a year. There appears to be every prospect that this large scheme will be very successful from a financial point of view.

Perth.—The new factory which has been in course of construction during the past year for Messrs. John Shields and Co., Limited, is now completed. It forms an extension fronting the Dunkeld Road to the north of the original works, and although divided from the latter by a fireproof wall and having a separate engine with separate driving power, it will be worked directly in conjunction with them. It covers an area to hold 250 looms, which, with 650 looms in the old works, will give a total of 900 looms. The heating system was fitted up by Mr. James Macleish, of Perth. All inside surfaces of walls are finished with white enamelled brickwork, and the

woodwork is of varnished pitch-pine. The new factory has been designed and carried out by Messrs. Robertson and Orchar, Limited, of Dundee, who were the engineers and architects for the original works. They have also supplied the whole of the iron-work, shafting and gearing, and a considerable portion of the looms, &c. The contractors were:—Mason work, Messrs. Robert Brand and Son, Perth; joiner work, Mr. Thomas Macaulay, Dundee; glazier work, Mr. Charles Alexander, Perth; plumber work, Mr. James Macleish, Perth; gasfittings, Messrs. Frew, Watson and Co., Perth; slater work, Mr. James Buchan, Perth; plaster work, Mr. John Peebles and Messrs. John Mackay and Son, Perth. Mr. Thomas L. Keay was the clerk of works.

Troon, Camborne.—The new mission church and schools which have just been built at Troon, near Camborne, in connection with St. John's, Treslothan, from designs by Mr. H. W. Collins, of Redruth, are in the Gothic style of the fourteenth century. The buttresses are of granite and the exterior facings are of pink elvan. The nave of the church is 45ft. by 25ft, the chancel is 24ft. by 18ft., while the schools are 56ft. by 24ft. In the east and west ends of the church are three-light tracery windows. The roof is of Oregon pine, the chancel arch is built in two colour stones, and the whole of the internal dressings are of Breage granite. The east window is of stained glass and has cost £140. The schoolrooms can be made into one large hall or four separate rooms at will, by means of patent folding screens. Between the schools and the church (which are connected by a corridor) is a cottage, consisting of nine rooms. The joinery is of pitchpine, and the floors of wood blocks. The ventilation is on Boyle's system, and there is a high-pressure heating apparatus. Messrs. W. C. Hodge, of Redruth, and F. Mitchell, of Leedstown, were the builders. The cost of the whole of the buildings will probably be about £3,000.

New Patents.

These patents are open to opposition until March 31st.

1899.—Sewage Purification.—2,373. W. M. DUCAT, London. In order to maintain bacterial action during cold weather, the incoming air is warmed by laying the air inlet pipes in channels in the floor of the filter bed. The invention is particularly applicable to the filter forming the subject of patent No. 654—1897, and No. 5,803—1897, and may be used above, or, if necessary, in conjunction with the method of supplying warmed air to the filter as described in patent No. 10,427—1898.

Travelling Cranes.—2,779. W. T. ROUNSIVELL, London, S.E. There is a carrier and there are rails similar to ordinary travelling cranes, but the carrier is provided at each end with sheaves, around which ropes pass to sheaves on the traveller and are connected with the lifting gear, which may be stationary. By those means a load in any place can be lifted. Transverse movement is provided for, and by pulling the chain attached to the block the latter is raised.

Manufacture of Tiles, Pipes, Bricks, &c.—4,241. J. PURVIS, London, E.C. Unslaked lime and sharp, clean, dry sand, or ground slag, are mixed in a receiver, and made to cohere by the introduction of steam. Moulding is then done, and the articles are placed in a heating chamber in an atmosphere of steam, the temperature being gradually raised to 80 deg. to 100 C., and maintained at that for about 70 to 100 hours. The temperature is then gradually reduced. A proportion of 12½ per cent. of lime, and 87½ per cent. of sand, or 15 per cent. of lime and 85 per cent. of slag, gives satisfactory results.

Closet Supply-Valve Fittings.—5,188. H. L. DOULTON, London, S.E. At the end of the closet supply-valve spindle is a perforated piston covered by a loose disc and enclosed by a casing. When at rest, the chamber below the piston is filled with oil. When the valve is shutting off, this oil is

forced through a port in the casing, and by this means the supply-valve does not return to its seat too quickly, producing concussion in the pipes.

Street Lamp-Posts.—10,699. W. JONES, London, S.W. Inside the lamp-post is a hydrant having two projecting nozzles, with a ground casing and cock at the side. There is also on the post a fire alarm.

Leaded Lights.—14,369. H. P. H. GILSON and W. J. BOVER, both of London, S.E. The fret lead used is convex on one surface and concave on the other, and fitted in it are india-rubber strips, of channel cross-section, between which the glass is held when the lead is pressed down. No cement, oil, paint, or putty is needed.

The following specifications were published on Saturday last, and are open to opposition until May 7th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1898.—23,078. WEISS (*Preble*), lathes or apparatus for turning or shaping wood, &c. 27,431. HASTIE and GILL, manufacture of cement.

1899.—393. GODSELL, glass cup protector for incandescent gas mantles. 1,935. MORGAN and TILLOTSON, apparatus for protecting and regulating the use of seats, and means for fastening and releasing them. 2,268. BROWN, cord grip for electric lamp holders and fittings. 2,451. BOULT (*Rosback*), step-mitering machines. 2,461. CAMERON, COMMINS and MARTIN, purifying sewage. 2,469. REDMAN, connecting incandescent burners to the gas supply. 2,517. REDMAN, supports for incandescent gas-burners. 2,800. BARTLETT, treatment of cork to form a composition suitable for use for structural purposes. 3,358. McCALLUM, shoes or pockets for ends of timber joists. 3,988. SMITH, blind rollers. 5,441. OSWALD, stop valves. 5,580. COWPER, manufacture of hinges. 5,806. WHYTE, BENTON and BENTON, locks. 6,051. KENT, gas lamps or burners. 6,103. WALLACE, ventilating cover for drain traps. 6,217. SWANSON, building construction. 6,275. ASHWORTH, blinds. 6,301. PRESTWICH, valves. 6,302. PRESTWICH, steam and water valves. 6,391. VERITY, springs of swing doors. 6,506. EVANS and LEWIS, valve apparatus for use with hydraulic mains and machines. 6,544. ARTHUR EDWARD HEATHCOTE, fireplaces. 6,714. CODD, exhaust-steam heating systems. 6,779. STAEGE and TORNOW, apparatus for heating water. 6,829. GWYNNE and SARGEANT, centrifugal pumps. 6,924. CHAPMAN, construction of partition walls. 7,033. McPHAIL, apparatus for heating water or for generating and superheating steam. 7,210. BREARLEY, regenerative furnaces for heating gas retorts, and the special construction of bricks to be employed therein. 7,325. READ HOLLIDAY ACETYLENE Co. Ltd., CARDNO and HOLLIDAY, apparatus for generating acetylene gas. 7,633. BRANDT, method of fastening metal sheets, laths, or strips on bars for building, fencing, and other purposes. 7,667. ADAMS, syphonic apparatus. 8,677. LAKE (*d'Este*), pressure regulating valves. 9,209. UPTON, electric arc lamps. 10,995. WILLIS (*Lowery and Billings*), windows. 13,645. KNIGHT, artificial stone slabs and cable channels. 18,353. KIELBERG, method and apparatus for casting cement pipes. 19,362. LEBODA, apparatus for impregnating long pieces of wood. 21,152. SCHALL, screw staples. 23,407. THOMPSON (*Marsh*), flush valves. 23,696. BROOKES (*Woodman and Fiske*), electric alarm systems for the protection of buildings. 23,948. DANDSARD, drying kilns for pottery and earthenware. 24,687. ALLISON (*Woodbury*), apparatus for flushing water-closets. 24,948. RANSFORD (*Basel Mission Tile Works*), ceilings. 24,949. RANSFORD (*Basel Mission Tile Works*), tiled roofs and new lining tiles therefor. 24,950. RANSFORD (*Basel Mission Tile Works*), roofing and wall covering tiles. 25,130. BUNN and CASE, manufacture of lead oxide and white lead. 25,144. GLEASON and POTTER, fire escapes. **1900.**—27. LYON and TALBOT-CROSBIE, electric arc lamps. 45. FEENT (*Allgemeine Elektrizitäts Gesellschaft*), electrical incandescent lamps of the newest type.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Earth Closets.

W. R. writes: "Where can I obtain inexpensive sealed night-stools, earth commodes, or other similar contrivances for sleeping apartments to vagrant cells?"

Write to Messrs. Nicholls and Co., 289, Strand, London, W.C.; Moule's Patent Earth Closet Co., Ltd., 5A, Garrick Street, London, W.C.; and Messrs. Young and Marten, Ltd., Caledonian Works, Stratford, London.

T. E. C.

Rain-Water Pipes.

NEWPORT, MON.—R. H. P. writes: "A house was purchased about six years ago from a certain builder, it being one of two which had only one r.w.p. between them. The builder has lately repurchased the adjoining house, and since coming into possession he has disconnected the eaves gutter and removed the r.w.p., so that my house is left entirely without a r.w.p. He has also given me notice that I must provide my own r.w.p., and that he will hold me respon-

sible for any damage done to his premises through the rain water going over it. Is his action legal, or should he provide my house with a convenience which was existing when I bought it from him?"

The builder's action is not a legal one. He is responsible to our correspondent for all damage caused by his conduct, and should be required to at once restore the premises to their former condition.

H. P. B.

R.I.B.A. Probationers' Examination.

NEWTON ABBOT.—MARTIN CHUZZLEWIT writes: "When will the next preliminary examination, qualifying candidates for Probationers R.I.B.A., take place, and where will it be held? Would a certificate of my having passed in the third-grade perspective (first-class), issued by South Kensington Department, exempt me from any part of such examination?"

The next preliminary R.I.B.A. examination will be held in June, 1900, from Tuesday, 12th, to Friday, 15th. The examination is held in London and also at several of the non-metropolitan centres, the latter depending upon the number of candidates presenting themselves in the various districts. The last examination was held in London, Birmingham, Bristol, Cardiff, Dublin, Manchester and York. The secretary, R.I.B.A., will inform candidates as to where they will be expected to present themselves for examination. With regard to the South Kensington certificate, it is rather doubtful as to whether exemption could be obtained. It would be best to write and ask the secretary, R.I.B.A.

R. W. C.

Etiquette in Tendering.

ST. ALBANS.—R. G. E. writes: "Having prepared drawings and specification for a proposed small addition to a house, I asked a neighbouring builder to tender, and at the same time to suggest to me any reduction in the design by which he could reduce the estimate without diminishing the

accommodation. This he has done, and I promised to write him further when it was decided whether to carry out the work or not. I now wish to write several builders to tender for the work, so as to get the estimate lower, if possible. Would not etiquette compel me to tell the builder who has already tendered of my intention, and invite him to submit a fresh tender with them, or should I keep his tender and compare it with the others when they arrive?"

Whichever of the proposed courses be adopted it would probably lead to discontent, and the only way to avoid this seems to be to pay the builder who has already tendered a small fee, such as would cover the expense he has been put to in tendering and the value of his advice, and then to prepare a new specification embodying his suggestions and any other alterations which may by this time be decided upon, and to invite tenders from him and others on the new basis.

G. A. T. M.

Proportional Compasses.

HARLESDEN, N.W.—ANXIOUS writes: "I should be glad to know what proportional compasses are used for, as I have a pair divided on both sides, but have never seen them used."

Proportional compasses have four sets of divisions on them. The first set is engraved "lines." If the sliding clamp be set at any number, say 3, on this scale, and the compasses opened to any extent, the long points will give a length three times that between the shorter points. Drawings can thus be enlarged or reduced to any proportion by

setting the compasses to the required number. The second scale is engraved "circles." The clamp being set to any number and the longer points opened to the radius of any given circle, the distance between the smaller points will divide the circumference into the required number of parts. The third scale is engraved "plans." The shorter points having been set to the length of the side of a square, the longer ones will give the length of the side of a square as many times greater in area as the number on scale to which it is set. The fourth scale, "solids," gives in a similar manner the lengths of the sides of cubes, the solid contents of which are in the proportion of the number at which the clamp has been set.

HENRY ADAMS.

Laying Floor Boards on Breeze-Concrete.

A. G. writes: "What is the best way to lay floor boards on breeze-concrete? How should they be cramped up? Should the concrete have a coat of tar a few days before the boards are laid? What sort of tar should be used?"

The boards may be nailed either on to fillets embedded in the concrete or direct on to the floor. Wooden fillets are generally used, and hold the nails well, but they are liable to decay, and should be creosoted if used at all. Floors of concrete, in which coke breeze is not an ingredient, have coke-breeze or composition fillets, which are preferable to wood. Whichever method is adopted, however, a thin layer of asphalt, bituminous sheeting, slag wool, or asphalted felt, must be laid to (a) form a slightly yielding bed to the traffic; (b) deaden the sound (concrete is a very good sound conductor); and (c) prevent dry rot. Tar would only prevent the latter evil. The concrete must be thoroughly dry before any boards are laid. If fixing joists and fillets are employed, the following methods for cramping up may be employed:—(a) If square headings are permissible "folding" can be employed, i.e., nailing two boards parallel with each

other at an interval slightly less than the width of three or four boards. The latter are then sprung into place by jumping on them. (b) If tongued headings are required, the boards would be laid separately, and wedged up from convenient fixed points formed by driving small timber dogs into the joists. (c) If the joists have to be glued, as in parquet floors, temporary blocks would be glued to the face of the first fixed parts and joiners' cramps used from them to draw up the remaining boards. (d) The commonest method is to drive a wide chisel into the joist at the edge of the board, and lever it up with one hand while nailing with the other. If the boards are nailed on to the concrete direct the "folding" method must be employed. Floor boards should be laid in dry summer weather. If laid in the winter, however tightly cramped, the joints will open in warm weather.

E. B. B.

Book on Cologne Cathedral.

GLASGOW.—J. B. writes: "I should be obliged if you would tell me of any book in which Cologne Cathedral is fully described. What I should particularly like to know is the position it holds as regards its architecture when compared with other principal continental cathedrals."

The merits of Cologne Cathedral are fully dealt with in Fergusson's "History of Architecture": Ancient and Medieval, a new edition, revised and enlarged by R. Phené Spiers; two vols., £2 9s.; Indian and Eastern, £1 5s.; The Modern Styles: the Renaissance to the Present Day; two vols., £1 5s. These volumes are obtainable from Mr. B. T. Batsford, 94, High Holborn, W.C.

Damp-Courses in Basement.

A. G. writes: "In using Tenax or Hygeian Rock Composition between walls as a vertical damp-course in a basement, is it necessary to adopt any precautions to prevent the two parts of the wall being forced apart when the stuff is poured in? If it is, what is the best method, having due regard to cost?"

The proper practice is to have a $\frac{1}{2}$ in. cavity and grout up with the composition at a height of every four courses. There is then no danger of the two skins of the wall being forced apart. To keep the cavity clear when building up, use a planed board. When the wall is over 9 in. in thickness the thickest skin should be on the inside of the wall. The composition can be poured into the cavity from a bucket, but care must be taken not to splash the face. It is a good plan not to carry the mortar in the brickwork right up to the cavity, so that the composition will key a little into the joints. This will prevent moisture finding its way down between the damp-course and skins of the wall.

E. B. B.

Income Tax.

CHESTER.—W. H. T. writes: "The other day I received a notice from the collector of taxes demanding payment of £3 6s. 7d. on eight houses, including the one in which I reside. Five of the houses are valued at £17 11s. per annum, one at £18 17s., and two at £19 10s., and the total rents received, including the rent of the house I reside in, amount to £2 16s. per week. The assessment is made under Schedule A two-thirds value as above at 8d. in the £. The property belongs to my wife, and I want to know whether, seeing that the property does not realise £160 a year, payment of the charges can be enforced. I am given to understand that the taxes are imposed on account of my wife's combined income since her marriage to me."

By section 45 of the Income Tax Act, 1842, 5 and 6 Vic., c. 35, where a married woman is living with her husband her income is to be deemed his income for the purpose of his assessment to the tax; consequently if the assessment on the house property, together with our correspondent's annual earnings, exceeds £160 a year, he is liable to income tax.

H. P. B.

WORKMEN'S COMPENSATION.

An Interesting Scaffolding Case.

THE case of *Mason v. A. R. Dean, Limited*, Moore and Sons, third parties, was recently brought before the Court of Appeal from the County Court of Lancashire. The applicant was the widow of Frederick William Mason, who had been killed in the course of his employment by a fall from a scaffold. His employers were A. R. Dean, Limited, furnishers and decorators, of Birmingham. The accident happened on February 10th, 1899, at the Lyceum Theatre, Eccles, near Manchester. The theatre was then an incomplete building, exceeding 30ft. in height, and it was being constructed by means of a scaffolding. Messrs. Moore and Sons had, prior to the date of the accident, contracted with the building owner for the construction of the building and for the erection of the scaffolding from which the deceased man fell. Under powers reserved in Messrs. Moore and Sons' contract the architect let off to Messrs. Dean certain decorative work. The scaffolding used by the deceased and his fellow-workmen was erected by Messrs. Moore and Sons at the expense of the building owner. At the time of the accident the deceased man was painting the ceiling of the theatre, and while walking on the scaffolding one of the planks gave way and he fell to the pit floor and was instantly killed. The respondents denied liability on the ground that the employment of the deceased was not an employment to which the Workmen's Compensation Act applied; and they also alleged that Messrs. Moore and Sons or their workmen erected the defective scaffolding, and were the persons responsible for the scaffolding. The respondents delivered to Messrs. Moore and Sons a notice of claim to indemnity against all liability on account of any accident caused by the scaffolding. At the hearing of the arbitration, before the arbitrator appointed by the County Court judge, it was contended on behalf of the applicant that the respondents were undertakers within the meaning of section 7, sub-section 2, of the Workmen's Compensation Act, and that they were engaged on work of construction in a building exceeding 30ft. in height, and then being constructed by means of a scaffolding. It was contended on the part of the respondents that the work which they had contracted to do was not work of construction within the meaning of the Act, and that they were not undertakers within the meaning of the Act. The arbitrator held that the respondents were undertakers, and that they were engaged in the construction of a building exceeding 30ft. in height, such building being then in course of construction by means of a scaffolding, and he awarded the applicant the sum of £300, with costs. At the request of the respondents the arbitrator stated a case for the opinion of the County Court judge, submitting the following questions:—(1) Whether the respondents were undertakers in the construction of a building within the meaning of the Act; (2) whether the Workmen's Compensation Act applied to the employment in the course of which Mason was killed. The County Court judge set aside the award of the arbitrator with costs, on the ground that, though the respondents were undertakers engaged in the construction of a building within the Act, yet the case of *Wood v. Walsh and Sons* (1899, 1 Q.B., 1,009) showed that painting the ceiling of the theatre was not an employment within the Act. The applicant appealed and the Court allowed the appeal.

Lord Justice A. I. Smith said that in his opinion the respondents were liable in this case. The Workmen's Compensation Act only applied to certain classes of employers, as shown by section 7, sub-section 1. Did it apply to the respondents? It applied to "employment by the undertakers, as hereinafter defined, on, in, or about any building which exceeds 30ft. in height and is either being constructed or repaired by means of a scaffolding or being demolished." Here the building was not completed. The respondents were put on to do certain work which would help to bring it to completion. The contract

of the respondents with the building owner showed that the work they had to do included the putting up of a ceiling, the erection of a proscenium, and the fixing of private boxes with columns, caps, &c. No doubt a good deal of the work was decoration pure and simple. But there was ample to show that they had also to perform structural work. The building was over 30ft. high, and it was being constructed by means of a scaffolding. It was clear that the deceased man was employed on a building within the Act. Was he employed by undertakers within the meaning of the Act? By sub-section 2 of section 7, "undertakers" meant in the case of a building the persons undertaking the construction, repair, or demolition. Ought that to be construed as meaning the persons undertaking the construction of the whole building or did it also include the persons undertaking the construction of a substantial part of a building? In his opinion a person who undertook the construction of a substantial part of a building was an undertaker within the Act. He therefore thought that the judgment of the County Court judge was wrong, and that the applicant was entitled to the compensation which had been awarded to her by the arbitrator.—Lord Justice Collins was of the same opinion.—Lord Justice Romer agreed. He thought that where a building was being constructed by several persons, not jointly, but each doing a separate part, each and all of them came within the definition of "undertakers" in section 7. But only that undertaker was liable to pay compensation in whose employment the workman was at the time of the accident.—The Court refused to allow the costs of the third parties.

Views and Reviews.

HELLYER'S "PLUMBING."

It is a testimony to the great value of this book that the demand has been such as to call for a sixth edition, which has just reached us. The book is now so well known that an extensive review will not be needed. This present edition has been revised and brought up to date, many new illustrations have been added while others have been changed, and a chapter has been written on "Cesspools and their Overflows," which, we are pleased to note, does not omit to deal with the septic tank treatment of the sewage, in respect of the purification of that from a mansion. The amount of information given by Mr. Hellyer is very large, but the book has not become too bulky thereby, nor is this wealth of information given at the expense of lucidity and usefulness.

"The Plumber and Sanitary Houses." By S. Stevens Hellyer. Sixth edition. 12s. 6d. London: B. T. Batsford, 94, High Holborn, W.C.

WAGES IN THE XIX. CENTURY.

This book is intended, not as a general history of wages, but as a text book for students of this branch of statistics, explaining by examples the methods to be pursued in arriving at reliable results. The method adopted in dealing with wages *en masse* is the "kinetic," consisting in studying not wages themselves, but their rates of change, making no attempt to construct a wage census for former dates or at the present time, but to study the proportionate changes of wages period by period, and combine the figures which indicate these rates of changes independently of the actual rate of wages at any time or place. This method is certainly preferable to the general method—the "statical"—which consists in making comprehensive estimates for given years, obtaining thus the average and distribution at those times, and finally comparing the results; for the "kinetic" method has the double advantage of making it possible to use all the material available and so obtain comprehensive results, and also of bringing into play special causes, tending to an accuracy lacking in the "statical" method, which, although perfectly sound in theory, is unfortunately difficult or impossible in prac-

tice. The section devoted to wages in the Building Trades is a most interesting one, and the tables given there will no doubt be found useful to trade union secretaries and others concerned with the keeping of statistics of wages.

"Wages in the United Kingdom in the Nineteenth Century." By Arthur L. Bowley, M.A., F.S.S. 6s. nett. Cambridge: University Press. London: C. J. Clay and Sons, Ave Maria Lane.

"THE PRACTICAL MAN."

The great value of this most useful little cyclopædia of information upon land matters affecting auctioneers, estate agents, surveyors and lawyers who may be concerned with business matters, is shown by the fact of it having reached its seventeenth edition in the fifteen years since it was first published. The work is in the handy form of a pocket-book, neatly bound in cloth, and is divided into two parts. The first part is most comprehensive for its size, containing information upon the many questions of Law of every-day occurrence in the form of short sections tersely worded and clearly arranged. The sections relating to various duties now payable on a death have been rearranged and amplified since previous editions, and are now all collected under the heading of Death Duties. Short abstracts of the principal statutes passed since 1884 have been inserted. We find most useful forms of agreement, such as for working a quarry, letting houses, to build a house, for building lease, and particulars of the various clauses of note in the Acts relating to such matters as Bankruptcy, Workmen's Compensation, Bills of Sale and Stamps. We have not space to do more than merely instance a few of the particulars given. The second part comprises matters of both general and technical interest, such as the rules for using logarithms, of which tables are also given, rules for measurements and calculations generally useful; tables and calculations of use in various trades; estate and property valuations; and many tables, with explanatory notes upon the methods of using them. This part has had a number of new calculations introduced in it, and the tables have been carefully revised by the editor, Mr. E. E. H. Birch, who has also added a full index, which renders this edition still more useful. For those who are often requiring information upon Law matters, this book is one of the most useful works one could have for ready reference.

"Rouse's Practical Man." Seventeenth Edition. Revised by E. nest E. H. Birch, B.A., Barrister-at-Law. London: Sweet and Maxwell, Ltd., 3, Chancery Lane, W.C.

Church Extension in Bristol.—The populous district of St. Mark, Easton, is shortly to be provided with a fourth mission church, to be dedicated to St. Anne. When the plans were prepared it was estimated that the building might be put up for £1,200, but the price of material has so advanced that it is probable the cost will reach £1,600 or £1,800.

Royal Female School of Art.—The annual distribution of scholarships, medals, certificates, and prizes to the successful students took place at the Fishmongers' Hall on Wednesday last. During the past year the students took eleven national awards, three of these being national silver medals, and twenty book prizes. A large number of works were marked for national competition, and five were retained for selection for the Paris Exhibition.

Manchester Sewage Scheme.—At last Wednesday's meeting of the Manchester City Council the report of the Rivers Committee dated January 22nd, 1900, was adopted, reserving to the Council the right to abandon the scheme if found desirable when the detailed plans, sections, and estimates of cost are placed before the Council. This embodies the provision of ninety-two acres of filter-beds for the treatment of sewage by double contact. The experts' reports have already been published in these columns (see supplements to issues for November 22nd, 1899, and January 31st last).

Under Discussion.

The Development of Archaeology.

Before a recent meeting of the Royal Dublin Society the Rev. J. P. Mahaffy, D.D., S.F.T.C.D., delivered a lecture on "The Development of Archaeology in the Nineteenth Century." He said that the archaeologists of the eighteenth century had come to be regarded, if not as destructive barbarians, at least as mischievous amateurs, who destroyed the most precious vestiges of ancient history. They were mostly patrons of art—men who professed so to admire classic art that they loved to transfer the most noble specimens to their gardens and galleries. Workmen were employed by those archaeologists to dig into the earth in likely places for statues and other remains of ancient art, and these were often taken up out of the ground in a mutilated condition, but that made no matter if they had clever workmen who could restore a broken nose or an arm where required. The archaeologists of the nineteenth century had made up their minds that it was better to leave such art treasures as they were found, rather than endeavour to improve them by any modern work. A recent French writer had characterised our private galleries and museums as "the tombs of ancient art," and so they truly were. Great quantities of beautiful work of early art had been carried off into the museums and private galleries throughout Europe, and so we had lost by that the benefit and instruction which might be gained if those things were shown in their proper places. The Venus of Milo was one example of the practice to which he referred, and owing to the way it was treated they were only in recent years able to discover the age to which it belonged. The climax of the archaeology he had been describing dipped into the early years of the nineteenth century by reason of the action of Lord Elgin, who took down the magnificent western pediment and a good part of the frieze of the Parthenon at Athens and brought them to the British Museum. Lord Elgin thought he was helping the cause of archaeology, and considered himself a patron of art, but the name by which these works of art were now known—the Elgin marbles—had for all time pilloried him, even as Pontius Pilate was pilloried in all Christian churches. The establishment of the Dilettante Society was the first sign of an improvement in this melancholy state of things. It consisted of a group of seven or eight or ten men, and they were the first, as far as he knew, to take a scientific view of archaeology. They sent out at least two first-rate architects, who by their efforts gave us a knowledge of Greek architecture we never possessed before. By the science of archaeology he meant the study and right understanding of the remains of antiquity. In no science had the successes been more glorified than in archaeology, yet they had been accompanied by severe losses—losses in our sense of beauty and sense of reverence for the sublime productions of the past.

Earth Foundations.

Mr. J. E. Pierce read a paper on "The Theory of Earth Foundations and its Application to Practice" before a recent meeting of the Ipswich Engineering Society. The first broad principle to be mastered when dealing with foundations was that all earths, with the exception of hard rocks, dry, hard earths, and such like, must be treated to a certain extent as liquids—i.e., they had a tendency to flow and level themselves as water did. If there was a tendency to flow, then there must be an approximation to a hydraulic pressure on going below the surface. Each different class of earth, when heaped up, had a constant slope with regard to the ground, and this was called its "angle of repose." It was very easy to see that a material of a very solid nature would necessarily have a large angle of repose, while a material of a soft nature (as sand) would have a small angle of repose. If you were dealing with an earth of great liquid

tendency, i.e., with a small angle of repose, it was easy to see that the foundation must be taken lower down before the displacement balanced the pressures on that foundation. A very appropriate illustration to show the liquid nature of some earth materials was afforded in the case of driving a number of short piles in soft ground, close to one another; it was noticed after several had been driven in, that if another pile were driven it caused some of those already in to rise out of the ground. He then dealt with Rankine's formula, which showed that the majority of the materials of a soft nature, such as sand (wet), clay and so forth weighed on the average about 110lbs. per cubic foot. Concrete weighed about 120lbs. per cubic foot. Further, the depth required varied directly as the pressure. The simplest bottom was that of a rock, though, if the rock were mixed with earth and clay, there was the liability of a treacherous foundation. "It is first necessary to level up the base, so that its plane is perpendicular to the pressure which it has to sustain, but if the structure is large and the rock surface uneven it is trenched up and down in a number of small faces. The unsound portions must be removed, and gaps and fissures filled with concrete, and when this is done, it may be built upon direct. Rock foundations are very expensive in working, owing to the great labour involved in levelling, &c.; still, they are very secure." Dealing with foundations on firm earth, the lecturer pointed out that the term "firm earth" usually meant gravelly soils, hard clay, hard earth, dry chalk, and dry sand. If the material was slightly damp the angle of repose would be larger, but if there was any likelihood of it getting saturated, then the angle was considerably reduced and the material no longer partook of the nature of solid ground, but more of the nature of a soft earth. These remarks applied very well to chalk soils, and the site for a building on chalk should be well-drained. If that was possible, the structure could be built direct on the chalk after it had been levelled, but if it was subjected to great loads, then concrete should be employed to distribute the pressure. If it was certain that no lateral movement could take place, gravel was one of the best soils to build on, and it was not affected by the atmosphere, as regarded expansion and contraction. It was best not to disturb the gravel by loosening it by digging, but rather to place the foundation right on the top of it. Clay was a very treacherous subsoil; under certain circumstances it was all right, but it was affected so much by atmospheric conditions that it must be very carefully treated. Clay expanded and contracted under the action of cold and heat, and a foundation on clay must be taken to a depth in some cases of 10ft., so as to keep the clay of a uniform dampness. Mr. Pierce gave some statistics in reference to the width and depth of concrete foundations, and observed that the great thing to be watched in a concrete foundation, or a foundation of stonework, was that no part of it should be subject to tensile stresses, as concrete was very weak in tension. He quoted a rule for ordinary foundations, so as to avoid tensile stresses—"That the resultant force of the earth's pressure on the base of the foundation shall be within the middle third for a square section, and within the middle quarter for a circular section." Any material whose angle of repose was less than 35deg. must be regarded as a soft earth, and as such it would have a tendency to escape laterally. In dealing with a foundation, it was absolutely necessary to have a section of the ground to guide us in planning out the best means of carrying out the structure. With regard to bad foundations, the lecturer said that if the bad ground was only, say, 6ft. or 7ft. deep, then the easiest way of getting over the difficulty was to excavate all the bad earth, and start the foundation on firm ground. If the depth of the bad ground exceeded 10ft., with a hard strata underneath, it was usual to either pile down to the firm ground, or make use of concrete piers of very great depth, and with these our foundation could be made by a sheet piling, to prevent lateral escape of the earth, or by forming the foundation on close planks.

Keystones.

The new Art Gallery at Hull will be completed next month and formally handed over to the Hull Corporation on April 2nd.

Mr. B. S. Murphy, a fourth year student at the School of Applied Art, Edinburgh, has just been awarded a £40 travelling bursary.

A new Clock Tower at Lewisham, S.E., 45ft. high, has been erected as a memorial of the Queen's Diamond Jubilee, and has cost £646.

A new Public Hall and Library at West Kilbride, N.E., has been built from designs by Mr. A. N. Paterson, M.A., A.R.I.B.A., of Glasgow, at a cost of £2,000.

A new Wesleyan Chapel at Wolverhampton, estimated to cost £13,000, is being built in Darlington Street, from designs by Mr. Arthur Marshall, of Nottingham.

Gladstone Memorial in London.—It is proposed that the memorial of Mr. Gladstone, designed by Mr. Hamo Thornycroft, shall be erected immediately to the west of St. Clement Dane's Church.

The Statue of Sir Sydney H. Waterlow, Bart., which is to be erected in Waterlow Park, Highgate, as a memorial of his gift of the park to the people of London, has now been completed by Mr. Taubman.

A new Wing to the Stanley Hospital, Liverpool, was opened on Thursday last. It has been erected from designs by Messrs. Duckworth and Medcalf, architects, of Liverpool. Messrs. J. and G. Chappell, were the contractors.

The Death is Announced of Mr. Horace Buttery, restorer of pictures to the Queen. He was held in esteem not only by private clients, but by the authorities of the National Gallery and of the Museums of Berlin and The Hague.

Barnsley Church Competition: Result.—In the competition for the erection of the St. Edward's Church, Kingstone Place, Barnsley, the first premium of fifty guineas has been awarded to Mr. Gordon S. Packer, of Southport; the second to Mr. E. Dyson, Horwick; and the third to Mr. C. S. Herrington, Newcastle-on-Tyne.

Society of Architects Badge Competition.—Designs may be submitted up to March 22nd next for a silver-gilt presidential badge, with attachment for ribbon and shoulder buckles; outside dimensions, 2½in. Members, associates and students of the Society of Architects are eligible to compete; two guineas will be paid for the design accepted.

Riviera and Italy.—By a pleasingly illustrated little pamphlet that has been sent to us we notice that one may obtain a first-class circular ticket (available for sixty days) from London, right along the coast from Marseilles to Genoa, and back again through Turin and Mont Cenis, for £10 1s. 1d. The Continental Traffic Manager of the London, Brighton and South-Coast Railway Company, London Bridge Terminus, S.E., will be pleased to supply all particulars.

R.I.B.A. Prizes and Studentships, 1900-1901.—The following is a brief summary of the R.I.B.A. prizes and studentships for 1900-1901:—*Essay Medal and Twenty-five Guineas*—The comparative desirability of the formal or irregular treatment of street architecture in large cities. *Measured Drawings Medal and Ten Guineas*—As usual. *Soane Medallion and One Hundred Pounds*—Design for a club house in a large city. *Pugin Studentship: Silver Medal and Forty Pounds*—As usual. *Godwin Bursary: Silver Medal and Forty Pounds*—As usual. *Owen-Jones Studentship: Certificate and One Hundred Pounds*—As usual. *Tite Prize: Certificate and Thirty Pounds*—Design for an entrance gateway to a public park. *Grissell Gold Medal and Ten Guineas*—Design for a timber foot bridge across a stream. *Asphitel Prize: Books value Ten Guineas*—As usual. *Arthur Cates Prize: Books value Ten Guineas*—As usual.

COMING EVENTS.

Wednesday, February 28.

SOCIETY OF ARTS.—Professor Carus-Wilson on "Pneumatic Despatch." 8 p.m.
 SANITARY INSTITUTE (Lectures and Demonstrations for Sanitary Officers: Part II.)—Mr. J. C. Thresh, D.Sc., M.D., on "Water Supply, Drinking Water, Pollution of Water." 8 p.m.
 EDINBURGH ARCHITECTURAL SOCIETY.—Mr. John Regg on "Johannesburg Before and After the War, from an Architect's Point of View." 8 p.m.

Thursday, March 1.

ROYAL INSTITUTION.—Mr. Charles Waldstein, Litt. D., Ph.D., L.H.D., on "Recent Excavations at the Argive Hereum (in Greece)."—I. 3 p.m.
 CARPENTERS' HALL.—Mr. C. Stanley Peach, F.R.I.B.A., on "Electric Light Stations." 8 p.m.
 ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Arthur Thomson, M.A., M.B., on "The Anatomy of the Human Form: The Connection of the Head with the Trunk; the Structures which Determine the Form of the Neck." 6.15 p.m.
 CIVIL AND MECHANICAL ENGINEERS SOCIETY.—Mr. M. O'Gorman, A.I.E.E., on "Ventilation of Large Buildings." 8 p.m.
 LONDON INSTITUTION.—Professor Silvanus P. Thompson, D.Sc., F.R.S., on "Electric Locomotion." 8 p.m.
 SOCIETY OF ANTIQUARIES OF LONDON.—Meeting at 8.30 p.m.

Friday, March 2.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Mr. H. D. Scarles Wood, F.R.I.B.A., on "Building Materials." 8 p.m.
 ARCHITECTURAL ASSOCIATION.—(Discussion Section.)—Debate on "The Question of the Modern By-Laws," opened by Mr. J. Humphrey Jones, B.A., Mr. J. H. Tyars and Mr. F. T. W. Goldsmith. 7 p.m.
 ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Lewis F. Day on "Ornamental Design."—IX.
 INSTITUTION OF JUNIOR ENGINEERS.—Mr. William Paddon on "Electrolytic Zinc as a Protective Metallic Coating for Iron and Steel." 8 p.m.

Saturday, March 3.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Inspection and Demonstration at the Express Dairy Company's Farm, College Farm, Finchley, at 3 p.m.
 BOUNDARY STREET AREA.—The Prince of Wales opens the Boundary Street Artizans' Dwellings of the London County Council.
 INSTITUTION OF JUNIOR ENGINEERS.—Visit to Messrs. Maudsley, Sons and Field's Belleville Boiler Works, East Greenwich, at 3 p.m.
 BRITISH INSTITUTE OF CERTIFIED CARPENTERS.—Visit to Royal Hospital, Chelsea, at 3 p.m. Prof. Henry Adams, M.I.C.E., on "Some Comparisons of Graphic Statics Applied to Roofs," at Carpenters' Hall. 6 p.m.

Monday, March 5.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Special General Meeting to elect Professor the Commandatore Rodolfo Lanciani, D.C.L., as the Royal Gold Medalist for the current year. Business Meeting to elect members.
 LIVERPOOL ARCHITECTURAL SOCIETY.—Mr. A. Saxon Snell, F.R.I.B.A., on "Public Baths and Wash-Houses."
 SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Mr. Percival Gordon Smith, F.R.I.B.A., on "Sanitary Building Construction and Planning." 8 p.m.
 SOCIETY OF ARTS.—(Cantor Lecture III.)—Mr. E. Sanger Shepherd on "The Photography of Colour."—I.
 ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Hugh Stannus, F.R.I.B.A., on "The Historic Evolution of Applied Art: XVII.—Renaissance Christian Art." 6 p.m.
 SOCIETY OF ENGINEERS.—Ordinary Meeting at 7.30 p.m.
 ROYAL INSTITUTION.—General Monthly Meeting at 5 p.m.

Tuesday, March 6.

ARCHITECTURAL ASSOCIATION OF IRELAND.—Mr. Thomas Drew, F.R.I.B.A., F.R.I.A.I., on "St. Patrick's Cathedral and its History." 8 p.m.
 GLASGOW ARCHITECTURAL ASSOCIATION.—Mr. James M'Kissack on "Through Normandy with Cycle and Camera." Election of Treasurer.

Wednesday, March 7.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Mr. George Reid, M.D., D.P.H., on "Sanitary Appliances," 8 p.m. Inspection and Demonstration at the East London Water Works, Lea Bridge, Clapton, at 3 p.m., conducted by Mr. W. B. Bryan, M.I.C.E.
 SOCIETY OF ARTS.—Dr. Carl Peters on "Macombe Country: Its Ancient Gold Fields and Industrial Resources." 8 p.m.
 BRITISH ARCHÆOLOGICAL ASSOCIATION.—Meeting at 8 p.m.
 EDINBURGH ARCHITECTURAL ASSOCIATION.—Mr. J. A. R. Inglis, A.R.I.B.A., on "Colour in Architecture." 8 p.m.
 NORTHERN ARCHITECTURAL ASSOCIATION.—Special meeting, open to members and associates in practice, to discuss questions of Professional Practice. Introduced by Mr. J. W. Taylor, F.R.I.B.A. 7.30 p.m.

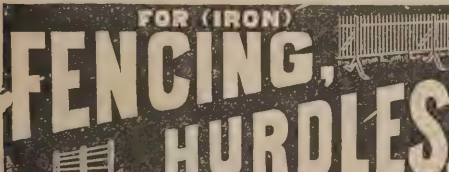

Thursday, March 8.

INSTITUTION OF ELECTRICAL ENGINEERS.—Meeting at 8 p.m.
 SOCIETY OF ANTIQUARIES OF LONDON.—Meeting at 8.30 p.m.
 CARPENTERS' HALL.—Mr. William Henman F.R.I.B.A., on "The Modern Hospital." 8 p.m.
 ROYAL INSTITUTION.—Mr. Charles Waldstein, Litt. D., Ph.D., L.H.D., on "Recent Excavations at the Argive Hereum (in Greece)."—II. 3 p.m.
 ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Arthur Thomson, M.A., M.B., on "The Anatomy of the Human Form: The Connection of the Head with the Trunk; the Structures which Determine the Form of the Neck." 6.15 p.m.
 SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.—Mr. E. Doran Webb, F.S.A., on "Salisbury Cathedral, and How it Came to be Built."

Friday, March 9.

ARCHITECTURAL ASSOCIATION.—Mr. C. E. Bateman on "Small Houses." 7.30 p.m.
 ROYAL INSTITUTION.—Professor Frank Clowes, D.Sc., F.C.S., on "Bacteria and Sewage."

TENDERS.

Information from accredited sources should be sent to "The Editor." No results of tenders can be accepted unless they contain the name of the Architect or Surveyor for the Work.

COLWYN.—Accepted for the erection of new stables and coach-house for Mr. M. Jackson, Norwood, Colwyn. Mr. Ashton Bremner, architect, Wynnstay Chambers, Colwyn Bay. Quantities by the architect.—

John Roberts, Colwyn Bay ... £320
COLWYN BAY.—Accepted for alterations and additions to banking premises, for the Metropolitan Bank of England and Wales. Mr. Ashton Bremner, architect, Wynnstay Chambers, Colwyn Bay. Quantities by the architect.—

J. Berth Jones, Colwyn Bay ... £290 10
EXMOUTH.—For alterations at "Donnington," Littleham Valley, for Mr. H. J. Cameron. Mr. Ernest E. Ellis, architect, Exmouth.—

T. Abell ... £243 18 7 | W. H. Perry ... £182 0 0
G. Hooper ... 195 0 0 | *Accepted.
EXMOUTH.—For the erection of a detached villa at Salterton-road (exclusive of road, &c.) Mr. Ernest E. Ellis, architect, Exmouth.—

H. Dart ... £1,000 | A. Hayman ... £290 0
G. Hooper ... 990 | W. J. Stokes ... 820
*Accepted.
EXMOUTH.—For alterations to Castle Park Cottage for Mr. J. J. Bastin. Mr. Ernest E. Ellis, architect, Exmouth.—

Cooper and Son ... £35 0 0 | W. H. Perry ... £320 0 0
W. J. Stokes ... 355 0 0 | H. Dart ... 320 0 0
H. J. Gay-Lang ... 355 0 0 | R. Cooper ... 319 0 0
F. Grace ... 347 11 6 | *Accepted.
GOMERSAL (Yorks).—For the construction of earthenware pipe sewers (400 yds.), &c., for the Urban District Council. Mr. John Waugh, C.E., Sunbridge Chambers, Bradford. Quantities by engineer.—

Thos. Egan and Sons ... £6,582 | Wm. Binns ... £5,590
Parker and Sharp ... 6,637 | Wm. Briggs, Frizing-
Wm. Waring and Son ... 6,390 | hall, Bradford ... 5,224
J. Bentley ... 6,140 | Morley and Barker ... 5,233
G. Pearson ... 5,965 | O. Metcalfe ... 5,222
W. and J. Foster ... 5,608 | *Accepted.
HEATON PARK (near Manchester).—For the extension of club premises, for the Heaton Park Liberal Club Building Company, Limited. Messrs. Maxwell and Tuke, architects, Manchester.—

Peters and Sons ... £1,175 | J. Leach and Sons ... £1,058
Bullivant and Sons ... 1,070 | G. Willison, Heaton
Jackson and Sons ... 1,070 | Park ... 1,048
J. Bland ... 1,059 | *Accepted.
LONDON.—For the rebuilding of No. 288, Edgware-road, W., for Mr. James Chambers. Mr. Eugene C. Beaumont, architect, 78, Fleet-street, E.C. Quantities by Mr. E. J. Gee, 30, Eldon-street, Finsbury.—

Holliday & Greenwood ... £4,077 | Cadman and Son ... £3,740
Grover and Son ... 3,933 | Patman and Fothering-
Henry Brown ... 3,877 | ham ... 3,741
George Neal ... 3,764 | Simpson and Son ... 3,690
*Accepted.

LONDON.—For the erection of a new warehouse, Marsh Gate-lane, Stratford, E., for Messrs. T. H. Harris and Sons. Messrs. J. T. Newman and Jacques, architects, 2, Fenchurch, E.C. Quantities by Messrs. C. Stanger and Sons.—

Outthwaite and Son ... £4,463 | Perry Bros. ... £3,987
Lark and Sons ... 4,359 | Green and Co. ... 3,750
Lawrence and Sons ... 4,155 | W. Gladding ... 3,687
G. J. Hosking ... 4,126 | Munday and Sons ... 3,617
Reed and Son ... 4,066 | *Accepted.

LONDON.—For the erection of a new school at Mandeville-street, for the London School Board, Mr. T. J. Bailey, architect:—

Leslie and Co., Limited ...	£23,972	+ £227
Miskin and Sons ...	23,957	+ 337
Gough and Co. ...	23,954	+ 300
Kilby and Gayford ...	23,780	+ 340
Clarke and Bracey ...	23,621	+ 318
Grover and Son ...	23,595	+ 349
T. L. Green ...	23,552	+ 270
Chessum and Sons ...	23,453	+ 320
Gregar and Son ...	23,378	+ 265
W. Goodman ...	23,328	+ 295
W. Shurmer ...	23,271	+ 298
L. H. and R. Roberts ...	23,204	+ 300
W. M. Dabbs ...	23,117	+ 305
J. and M. Patrick ...	22,832	+ 252
Patman and Fotheringham, Limited	22,878	+ 282
Lawrence and Sons ...	22,756	+ 271
C. Cox ...	22,688	+ 285
Edwards and Medway ...	22,593	+ 232

* Accepted.

† Additional if walls of classrooms and halls are plastered.

LUTON.—For the erection of factory in Victoria-street, for Mr. W. A. Sharp. Mr. A. Wilkinson, architect, 84, Inkerman-street, Luton:—

A. Mardle ...	£316 10	G. Kingham ...	£253 18
D. Parkins ...	299 15	[All of Luton.]	

* Accepted.

LUTON.—For the erection of residence, "The Downs," for Mr. Tomlin. Mr. A. Wilkinson, architect, 84, Inkerman-street, Luton:—

Hill and Foster ...	£878	Saunders and Son ...	£710
G. Kingham ...	875	A. Mardle ...	699
T. Field ...	810	[All of Luton.]	

* Accepted.

† Too late.

PLAISTOW (Kent).—For the erection of north transept and enlargement of vestries, &c., St. Mary's Church, Plaistow, Bromley, Kent. Messrs. B. Wadmore and W. R. Mallett, architects, Chancery-lane, E.C.:—

D. Payne ...	£2,469	A. Arnold and Son ...	£2,230
Goddard and Son ...	2,319	S. D. Grady ...	2,065
Crossley and Son ...	2,238		

STYRRUP (Notts).—For the erection of the "White Swan" Inn, Styrrup, for the Workop and Retford Brewery Company. Messrs. Vallance and Westwick, architects, Mansfield:—

Vickers, Ltd. ...	£2,960	0 0	John Athron ...	£2,740	0 0
J. Hutchinson ...	2,850	0 0	A. Eastwood ...	2,500	0 0
Fisher Bros. ...	2,834	0 0	D. Gill and Son,		
J. F. Price ...	2,809	12 3	Doncaster ...	2,387	0 0

* Accepted.

SUTTON-IN-ASHFIELD.—For additions to Oddicroft Mill, Sutton-in-Ashfield, for Messrs. Barringer Wallis and Manners. Messrs. Vallance and Westwick, architects, Mansfield:—

J. Hutchinson ...	£3,483	15 0	J. Greenwood ...	£2,796	7 6
J. F. Rice ...	3,342	5 0	Vickers, Ltd.,		
Fisher Bros. ...	3,065	17 10	Nottingham ...	2,667	10 0

* Accepted.

TIVERTON (Devon).—For the execution of sewage works, West Exe, for the Corporation. Mr. J. Siddalls, Borough Engineer, Town Hall, Tiverton:—

S. Manning ...	£3,261	1 11	J. and T. Binns ...	£2,235	11 0
R. H. B. Neal ...	2,875	0 0	Thomas & Webb,		
Grater and Sons ...	2,845	0 0	Bristol ...	1,923	5 1
E. Powell ...	2,255	10 3	F. Wood ...	1,811	16 0

* Accepted.

TORWORTH.—For making alterations to the "Huntsman Inn," Torworth, for the Workop and Retford Brewery Company. Messrs. Vallance and Westwick, architects, Mansfield:—

J. F. Price ...	£2,715	0 0	Fisher Bros. ...	£2,298	0 0
Dennis Gill and Son ...	2,546	0 0	J. Athron ...	2,263	0 0
A. Eastwood ...	2,330	0 0	R. Mettam,		
J. Hutchinson ...	2,322	0 0	Retford ...	2,188	0 8 1/2

NON-FLAMMABLE WOOD

Or Wood that has been chemically treated so that it Won't
Catch Fire and Won't Spread Flames.

The London Non-Flammable Wood Co. Ltd.

beg to announce that their works in London, the first erected in Europe, are now complete, and they are prepared
to supply Non-Flammable Wood in any quantity.

NON-FLAMMABLE WOOD.

BOARDS HAVE BEEN OFFICIALLY TESTED BY THE BRITISH FIRE PREVENTION COMMITTEE.

The Committee's Report says:-

"No Incandescence or spread of flame was observed, nor did the material, as far as could be seen, contribute in any way to the spread of flame. The surface of the boards was charred."

NON-FLAMMABLE WOOD JOINERY and CABINET WORK has been specified by leading Architects, and the Company has fulfilled orders for the Royal Yacht, the Admiralty, the Crystal Palace, Mr. Wyndham's Theatre, etc., etc.

LIFT-SHAFT LININGS FOR FLATS AND HOTELS.

Use Non-Flammable Wood Matchboarding.

NO FIRE RISKS. NO PLASTERING. NO WASTE OF TIME.

Quotations will be furnished on receipt of Specifications.

THE LONDON NON-FLAMMABLE WOOD COMPANY Limited,

Regent House, Regent Street, London, W.

EXPANDED METAL.*

By WILLIAM J. POATE.

EXPANDED metal is not, by any means, an innovation, as it was first produced in commercial quantities about twelve years ago; prior to its advent, the only means of producing open metal work were either by casting or by interweaving wires, rods, or bars. Expanded metal is produced by a method directly the contrary to these, namely, by partially cutting a solid plate of metal into strands having uncut connecting intersections and spreading the metal apart at the cuts into the sizes and forms of open work required; a plate of metal is thus expanded to cover a greatly increased area.

Manufacture of Expanded Metal.

At first the machines were unable to supply expanded metal more than $\frac{1}{10}$ in. thick, for, although they would cut and open the metal simultaneously, the perfecting of the details of the machine had still to be accomplished, and the knowledge of suitable metals for cutting and expanding had to be acquired. Consequently, the use of the metal was restricted almost wholly to lathing for plastering. The necessity for heavier metals and for greater accuracy in cutting was of vital importance. Considerable sums of money were spent in improvements, and the result was the addition of another patented machine, which operates alike upon the thinnest or thickest metals with great precision. The framework of the machine consists simply of a large guillotine shear, the upper V-shaped cutters being operated from the main shaft by means of eccentrics attached to the sliding head. The lower blade of the machine is straight. In operation, the V-shaped cutters make a downward stroke and carry before them a strip of steel, leaving spaces of intervening metal uncut. The cutters then rise and the plate is automatically moved into position, so that the uncut spaces are immediately under the cutters, which again descend, forming another half mesh and completing the first. The machine works rapidly and clears itself, throwing the metal on the floor.

The size of the cutters determines the size of the mesh, and the width of the strands is determined by the distance the plate of metal is fed over the lower straight cutter. It requires the same strength and weight of machine to make a small mesh as a large one, as there are more slits and stretches in the smaller meshes than in the large. To alter the size of the mesh it is only necessary to change the upper corrugated cutters. As the machine produces the expansion by stretching the strands as they are cut, the finished article is consequently of the same length as the original strip of metal, while it is increased from twice to twelve or more times in width; that is to say, a sheet of steel 8 ft. long by 6 in. wide can become a sheet of expanded metal 8 ft. long by

FIG. 1.

FIG. 2.

6 ft. wide. In practice it is necessary to bear in mind that the long way of the mesh is the strongest way.

Expanded Metal in Concrete Floors.

The typical construction of concrete floors on the expanded metal system may be divided into the three following classes:—(1) That in which the metal and concrete are laid over the joists, as shown in Fig. 1; (2) that in which the metal and concrete are laid on the lower flange of the joists; (3) that in which the concrete and metal floor are supported by and carried over the tops of concrete spandrels and steel channel-ribs. The first system is the cheapest, lightest, and simplest for floors of moderate strength, in spans up to 8 ft. between the girders—say for offices, hotels, schools, &c. In fixing this floor the temporary centering is easily supported by the bottom flange of the joists, whilst the continuous flooring slab thus formed is not liable to crack away from or over the girders. You will observe in Fig. 1 that the expanded metal is laid immediately over the wood centering, the

and those in various other buildings have been carried out on this system.

The system shown in Fig. 3 is patented, and is especially applicable to strong warehouse floors or for bridging over spans of, say, 10 ft. to 20 ft. without the use of intermediate joists, whilst preserving a maximum head-room. The channel arches are usually placed 4 ft. or 5 ft. apart, and are 6 in. wide, weighing about 12 lbs. per foot run. The concrete is built up on these to the level of the top flanges of the main girders. The 3 in. mesh is then laid on and covered with concrete as in the first system.

The channel-arch system has been extensively used in the Manchester Ship Canal warehouses, where there are several acres of floors of this description. In practice the channel-arch floor can be constructed to support a live load of 20 cwt. per square foot, and as the cost is less than other systems it is evident that for heavy warehouses, factories, &c., it cannot be excelled.

System No. 1 is now being employed in the new premises being built for the Eagle

FIG. 3.

long way of the mesh crossing the rolled steel joists at right angles. When the concrete is laid on and tamped down the finer particles are forced under the expanded metal, slightly raising it, and thus forming a tension bond in the lower strata of the concrete floor. The weight of the slab may not exceed 20 lbs. to 25 lbs. per square foot of area. The floors and roof of the Southampton Theatre are carried out in this manner, with girders at 5 ft. centres; average thickness of concrete 2½ in. to 3 in.; and ingredients 4 of coke breeze to 1 of cement, laid on 3 in. mesh by ½ in. by ½ in. metal.

A floor constructed on the system illustrated at Fig. 2 may weigh from 30 lbs. to 40 lbs. per square foot of area, according to the depth of the joists. The 3 in. mesh is laid lengthwise across the lower flanges, and when the concrete is filled in and set the whole structure is securely locked together. The 3 in. floors of the Ivy Lodge Residential Flats, Fulham (joists 6 ft. apart, concrete 4 to 1 formed on 3 in. mesh $\frac{1}{10}$ in. by ½ in.)

Insurance Company in Colmore Row, Birmingham (architects, Mr. W. R. Lethaby, London, and Mr. Ball, Birmingham), and in the new composing room for the "Birmingham Daily Post," the girders being 35 ft. long and spaced at 6 ft. 9 in. centres; concrete 4½ in. thick laid on 3 in. mesh. System No. 2 is being carried out at premises for the Birmingham Mutual Bakery in Allesley Street, and at the new ice factory at Digbeth. I may add that steel embedded in cement is practically imperishable, and the expanded metal supplies to the concrete what it generally lacks—tensile resistance. With reference to tests made on concrete blocks with and without expanded metal, the summary of the report of Messrs. Fowler and Baker (the eminent engineers) shows that in the case of a 3 ft. 6 in. span expanded metal increases the strength of the slabs for carrying a uniform load from six to eight times; in the case of a 6 ft. 6 in. span the strength is increased from ten to eleven times.

Expanded Metal in Solid and Hollow Partitions.

The 2 in. solid partition is constructed by fixing tension rods at about 1 ft. centres from

* A paper read before the Birmingham Architectural Association on February 16th, 1900.

FIG. 5.

the floor to the ceiling (as shown in Fig. 4), on the line of the partition, and interlacing the mesh of expanded metal into the rods. It is then plastered on one side and a considerable key may be forced through it, forming the groundwork for the plastering on the other side; so that a partition built up in this manner is very cheap. It takes up a very small space and does not require a foundation for it to be built upon, which is an essential factor in many cases. It is not always possible to get a foundation beneath partitions, as they may be needed where there are no girders. The sound-proof qualities of these partitions have been tested and found to be quite equal to 4½ in. brickwork partitions. Other advantages of the 2 in. solid partition are—a saving of 66 per cent. of space and of more than half the weight of a brick wall. It is not essential to use expensive patent plaster in the construction. Some of the best examples have been plastered with ordinary “gauged” lime mortar. At New College, Oxford, most satisfactory results were obtained with partitions over 12 ft. high, the composition being 1 of Newberry lime to 1 of limestone and 1 of gravel, mixed in a mortar mill and gauged with 30 per cent. of plaster of Paris. Examples of the 2 in. solid partition may be seen at the Grand Hotel, Colmore Row, and at the Hen and Chickens Hotel, New Street, Birmingham.

The hollow partition is formed of light angle-iron standards fixed about 12 in. to 14 in. apart, with adjustable clips to steel joists at the top, and spiked down at the bottom to the breeze-concrete floor. Lathing clips are attached to the standards 6 in. apart and the mesh fixed on each side. This presents a rigid ground for the plaster, which is applied ¾ in. thick, making the total thickness about 4½ in. to 5 in. In the hollow partitions the angle standards are more in compression, whereas in the 2 in. solid partition the tension rods have to be strained taut. Several partitions of

FIG. 4.

FIG. 7.

this hollow type are now in course of construction at the new premises for the Eagle Assurance Company in Colmore Row (of which the architect is Mr. Ball, Edmund Street, Birmingham).

Suspended Ceilings.

In most flooring systems where sound and fireproof efficiency is required it is desirable or necessary to use suspended ceilings, the air space between them and the floor being one of the best-known non-conductors. The method

FIG. 6.

of applying expanded metal ceilings is very simple and is illustrated at Fig. 5, where the details are clearly shown, the circulating air space being the full depth of the rolled-steel joists. The steel clips and hangers are first attached to the bottom flange of the joists; the lathing bars are next placed in position, spaced 12 in. apart; the hangers are closed firmly on the bar; the mesh is then laid on and secured to the bars with small steel clips, the latter being spaced about 6 in. apart; and, lastly, the plaster is applied, usually in three coats, to bring up a total thickness of ¾ in.

Plaster for Expanded Metal.

Practically any of the plasters used in the trade may be applied to this metal fabric, but it is necessary that the first coat (or rendering) should be free from all acid or corrosive ingredients. The second and third coats not being directly on the metal, such properties are of little consequence. A satisfactory mortar or lime plaster may be formed of 1 part of well-burned fresh slaked lime and 1 or 2 parts of clean, sharp pit or fresh-water sand, with which should be thoroughly incorporated 1 lb. of dry, long, well-beaten hair to every three cubic feet of plaster. This mixture may be gauged with a small quantity of Paris or Portland cement to accelerate setting. To

prevent waste pressure should be avoided when applying it to the ceiling. The finished surface may be whitewashed, painted, or papered, according to taste.

The great advantage of expanded metal lathing, irrespective of its fire-, damp- and insect-proof properties, is the excellent key it affords for the plaster, combined with every facility for moulding, cutting, and attaching to wood or ironwork. It also prevents the plaster cracking under the influence of unusual heat, which constantly occurs in ceilings where wood laths are used. In ordinary wood floors the metal lathing is often used by directly attaching it to the underside of the wood joists with staples or spikes. Expanded metal is also used for many other purposes, such as encasing columns and stanchions, as shown in Fig. 6; no system of fire-resisting construction is efficient unless the steel and ironwork is properly encased. It is also largely used for outside construction in America (see Fig. 7). A building on this principle has recently been completed at the Gas Works, Dublin. [We are indebted to the Expanded Metal Company, Ltd., of 39, Upper Thames Street, E.C., for our illustrations].

A Lecture on Sewage Disposal was recently delivered at Sheffield by Mr. S. H. Adams, of York, before the Association of Sanitary Inspectors. After dealing with the earlier methods of sewage disposal, he described the Fosse system of Paris, and the manufacture of sulphate of ammonia at Bondy. Whilst fully appreciating the advantages pertaining to various systems, the lecturer expressed his feeling that from a combination of what was known as the holding-up or contact system and a septic or resolving tank the best—that is, the most reliable—results were obtainable. Where sewage was simply treated in transit of a limited time through a filter, bacterial agency was also limited to the time occupied by the sewage in transit; then if this sewage were long in transit the filter would apparently become a holding-up filter of doubtful construction, whereas on contact beds sewage might be retained until actually purified, regardless of the nature of the sewage itself. The advantages of the first settling tank lay in the fact that as far as possible all organic matter would be (if the tank were large enough) in solution before the liquid was put upon the beds. It was undoubtedly the case that many sewers served the purpose of the resolving tank; this and the varying conditions governing the work would show that no fixed rule was applicable to all, but that each installation should be dealt with according to the exigencies of the case.

Builders' Notes.

The death is announced of Mr. Ben Gooden, stone merchant, Brighouse. He was well known in the Yorkshire stone trade, and was highly esteemed.

The Lowestoft Master Builders' Association held its first annual dinner on Thursday last. The Mayor, Councillor E. E. Johnson, presided.

The death is announced of Mr. Ralph Platt, of Southport, at the age of eighty-one. He was a brickmaker who, it has been estimated, supplied over two hundred million bricks to Southport.

New Board School for Pudsey.—Plans have been passed for the new board school for the southern part of Pudsey, to be erected in Valley Road, Littlemoor, at a cost of about £7,000. The tenders have been let as follows:—Mason, John Ambler, Pudsey, £3,180; joiners, E. Hutton and Son, Fulneck, £2,130; plumber, W. Barrand, Leeds, £675; plasterers, Laycock and Son, Pudsey, £170; slaters, Hill and Wilson, Bradford, £360; painter, G. H. Smith, Pudsey, £98.

Cartwright Memorial Hall, Bradford.—It is stated that in consequence of increases in the prices of the various classes of building material and labour, the plans accepted for the Cartwright Memorial Hall in Bradford, which were originally estimated to cost £38,000, cannot now be erected for less than 25 per cent. more. It will be remembered that Lord Masham gave £40,000 for the erection of the hall in Manningham Park, and the question now being discussed is, will Lord Masham's gift have to be supplemented out of the rates, or other plans substituted?

London County Council.—In the course of a long report the Improvements Committee stated that the length of frontage of the buildings which would face the northern side of the widened Strand would be 850ft.; the frontage of the southern side of the new crescent would be 1,080ft.; whilst the length of frontage on the northern side of the crescent from Wellington Street to St. Clement's Inn would be 1,220ft. The length of the frontage on the eastern side of the main street from the crescent to Holborn would be 1,430ft.; on the western side 1,300ft. The total length of frontage therefore of the new buildings which would be erected in connection with the complete improvement would be 5,980ft., or nearly 1½ miles. The recommendations of the Committee with regard to inviting designs from eight leading architects and controlling the architectural features of the new thoroughfare (full particulars of which were given on page 42 of last week's issue) were postponed for a fortnight.

Solicitors as Builders.—On Thursday last at the London Bankruptcy Court the public examination was held of Arnold, Sismey and Arnold, London, solicitors, carrying on business under the style of Keighley, Arnold and Sismey. They filed their own petition and furnished a joint statement of affairs showing a total indebtedness of £364,001, of which £278,652 was treated as fully secured and £86,187 as likely to rank, the assets being returned at £21,177, including an estimated surplus of £12,912 from securities held by creditors. It appeared that in and subsequent to 1895 the firm acquired certain building sites and house property in the City and West End of London, and had since been engaged (mainly with the aid of borrowed money) in building operations of great magnitude, which had been the cause of their failure. A scheme providing the payment of a composition of 7s. 6d. in the pound has been accepted by the creditors. The hearing was adjourned for three weeks.

Surveying and Sanitary Notes.

Cost of Clearing Snow from Streets.—The St. Giles's Board of Works have spent this month an additional £320 for labour and £455 for cartage in clearing away the snow from the streets in their district.

Sanitary Institute Congress and Exhibition.—The Sanitary Institute has resolved to postpone the congress and exhibition arranged for the present year at Nottingham, owing to the large responsibilities placed upon the country by the war, and their probable effect on the success of the exhibition.

Surveyors' Institution.—It has been decided, on the invitation of the Yorkshire Provincial Committee, to hold the next county meeting at Leeds, on April 25th and 26th. The first day will be devoted to papers and discussions, with a dinner in the evening; the second day to excursions to various places of interest in Leeds and its neighbourhood.

The Annual Dinner of the Surveyors' Institution was held last Wednesday evening at the Holborn Restaurant, the president, Mr. T. M. Rickman, occupying the chair. Mr. Jesse Collings, M.P., said the Institution was established thirty-two years ago and now had 3,000 members. The new building in Great George Street had cost nearly £40,000, and had a library of about 10,000 volumes.

Insanitary State of Dublin.—In the course of the Local Government Board enquiry into the public health of Dublin, Mr. Maguire, formerly chairman of the Public Health Committee was examined last week. He said that, taking all of Dublin, no unprejudiced engineer would pass more than half of the houses, new and old, including Merrion Square and all the other squares and streets in the city.

Decision Affecting Roads.—The North British Railway Company appealed against notices requiring them to execute granolithic pavements in Bothwell, Glasgow. Sheriff Principal Berry recently found for the company, holding that the notices go beyond what is authorised by statute, which authorises the repair and not the formation of either highways or footpaths.

Leeds Street Improvements.—The Leeds Improvements Committee has decided to recommend the City Council to spend £67,000 on the purchase of various properties required for public improvements in Duncan Street, Smithies Street, Wade Lane, Woodhouse Lane, Lands Lane, Meadow Road, Easy Road, Brunswick Row, and Back Nile Street. It is intended to demolish a large portion of the property on the north side of Duncan Street with a view to making that thoroughfare of the same width as Boar Lane.

Prosecution for Insufficient Lavatory Accommodation.—At Burslem, Staffs., last week, before the stipendiary magistrate, Messrs. Doulton, Limited, were charged with "failing to provide and maintain sufficient and suitable washing conveniences for all persons employed in dangerous processes, as near as practicable to the places in which such persons were employed." Miss Deane, H.M. Inspector, proved that on January 16th last, when she visited the factory in company with Miss Anderson (H.M. Principal Lady Inspector of Factories) she found that in the lower works, where fourteen workers were employed, no lavatory accommodation was available, and that in the upper works a trough with waste-pipe, containing four loose basins and with five taps, was provided for the use of thirty-five workers. Mr. Baily, manager for Messrs. Doulton, gave evidence that alterations were in progress which would include increased lavatory accommodation.—The case was dismissed.

Local Authorities and Private Drains.—An important decision under the Public Health Act was given on Thursday in the Court of Appeal when the case of *Sykes and another v. The Sowerby Bridge Urban Sanitary Authority* was decided. The plaintiffs had

constructed a drain to carry off the surface water which flooded the land, and did great damage in the neighbourhood of the stone quarry, of which they were owners. The Sanitary Authority claimed that they were entitled to use the drain, basing their claim on the Public Health Act of 1875. An injunction against the authority had been obtained in the Halifax County Court, but this decision was reversed in the Divisional Court and that decision was now appealed against.—Mr. Lawson Walton, in arguing in favour of the decision in the Court below, based his argument on the fact that the drain discharged itself into a public sewer.—Lord Justice Smith, in giving judgment, said he had no doubt that the drain was a sewer within the meaning of the Public Health Act of 1875. He quoted the section of the Act governing the appeal, and said the point at issue was the meaning of the words "his own profit." As the plaintiffs had made this drain so that their quarry might be rid of the surface water for the more profitable working of the land, the Queen's Bench were wrong in holding that it was not constructed for the profit of the owners, and in his opinion the drain did not vest in the local authority.—Lords Justices Collins and Romer concurred, the latter holding that if the decision of the Divisional Court had stood the result would have been that all agricultural drains throughout the land would have become vested in the local authorities.—Judgment accordingly.

Engineering Notes.

The new line of the City and South London Electric Railway to Moorgate Street was opened for traffic on Monday last.

Mr. Peter Schuyler Bruff, who was for many years one of the best-known civil engineers in the eastern counties, died on Saturday last at Ipswich.

"Portable Pneumatic Tools" was the title of Mr. Ewart C. Amos' lecture before the Institution of Mechanical Engineers last Thursday. Valveless hammers have essentially a short stroke, and, although economical in air consumption in relation to the number of blows given, they will not compare with valve hammers in giving powerful blows, which is necessary in heavy chipping or riveting. Owing, however, to their simple construction, they have probably a longer life than the valve hammers, and for such purposes as beading flues, light caulking and chipping, and especially carving in stone, they compare very favourably with their rivals. Riveters, drills, hoists, jacks and shears were also dealt with in the lecture.

Proposed Central Water Board.—At the recent half-yearly meeting of the British Association of Waterworks Engineers (Mr. W. Watts, of Sheffield, presiding), Mr. C. E. Jones, of Leyton, Essex, read a paper in the course of which he advocated the creation of an independent National Water Board, which should include representatives of law, geology, hydraulic engineering, chemistry and meteorology, and possess wide-reaching controlling powers. The coupling-up of distributing mains and other apparatus in contiguous towns or systems should, he said, wherever practicable, be made compulsory; but it seemed hopeless to expect that this combined action would ever be attained except by the intervention of some duly constituted central authority. It took the London water companies half a century to recognise the value of intercommunication, and ultimately a State department had to enforce its adoption. He suggested that the London companies might be advantageously amalgamated. He submitted that the monopolization of gathering grounds by powerful and wealthy corporations was a growing evil, fraught with peril to smaller communities, and requiring the immediate attention of the legislature. As to the scheme for "tapping" Wales for the benefit of London, he contended that the provision of additional storage capacity in the present watersheds would relegate schemes of this character to the dim and distant future.

Masters and Men.

The Dundee Plumbers have determined to resist the proposed reduction of their wages from 9d. to 8½d. per hour.

Reduction of Wages at Stirling.—The master builders have resolved to reduce the wages of masons and joiners by 1d. per hour, and the plasterers, plumbers and slaters by ½d.

The Dundee Masons struck last week on account of the masters holding to their determination to reduce the wages of hewers from 9d. to 8½d. per hour and of builders from 9½d. to 9d. About 400 men are out, although eight non-associated masters have agreed to continue the wages.

Plumbers' Strike in Bradford.—Some 200 plumbers came out on strike last Saturday week at Bradford, for an advance in wages from 8d. to 9d. per hour. The masters have intimated that they are prepared to pay 8½d. per hour, provided the men agree to the stipulations that they shall start on the job or at the shop at the discretion of the employer; that work shall cease at 4.30 p.m. for three weeks before and three weeks after Christmas, and at five p.m. for the three weeks before and three after the six weeks mentioned; the men taking an hour instead of half-an-hour for dinner.

The Aberdeen Building Trade Dispute.—In view of the present depression in the building trade of this town the masons have agreed to a reduction of ½d. per hour in their wages. With regard to the painters the masters have intimated to the men that they are prepared to terminate the dispute on the following terms:—(1) The option on their part to pay the journeymen in their first year, and the old men 1d. or ½d. less per hour than the standard wage; (2) the deletion of the by-law referring to the payment of wages for suburban work.

The Recent Stormy Weather put a complete stop throughout the country to building operations, but has provided the small tradesman with an almost endless list of small jobs. Meantime the more regular class of builder is affected by the high prices of materials, and is postponing his works to a more favourable season, when he reckons upon seeing prices fall. The brickmaker and the timber merchant, on the other hand, are not so confident that a fall will take place. In the latter trade, it is true, some of the younger firms at the Humber ports have been selling "to arrive" at low prices, but in doing so they are speculating upon a fall which has not yet been established. Timber orders, meanwhile, are increasing, and, although the stocks at the ports are large, all the spring consumption is to come, and a good demand is inevitable, so that prices may even harden.

Trade and Craft.

Welsbach Gas Lighting.

Everybody knows of the revolution in gas lighting which has been caused by the introduction of the incandescent mantle, and there can be "no possible doubt whatever" as to the improvement effected. When Auer von Welsbach first made his discovery that it was possible to construct a mantle with the rare earths that would give a light ten times as great as that obtainable with the old gas burners, he little thought perhaps of the magnitude which his invention would attain. Comparing the two, we find that while the ordinary open flame burner gives about two or three candle-power per cubic foot of gas consumed, with the latest type of Welsbach burner it is possible to have a light of more than twenty-five candle-power for the same gas consumption. This point need not, however, be emphasised, for, whatever may be the opinion held with regard to other factors, it is now universally admitted that, as a gas light, the Welsbach has no equal. What people have argued about is the mantle itself. There is no use disputing the fact that this is still a fragile article and requires careful handling; yet, when it is looked after properly, it will stand for a considerably longer period than the opponents of the Welsbach system are prepared to admit. It is interesting to note at this juncture, in view of the litigation which has arisen in connection with the mantle (in which, however, the Welsbach Company have been successful all along the line), that there are three principal patents—the 1885 patent, which expired in December last; the 1886 patent, which expires next March; and the 1893 patent, which will expire in January, 1907. The last patent is, at the present time, of the most consequence, as it was in 1893 the discovery was made that by adding a small percentage of ceria to the thorium (the use of which constituted the 1886 patent) a greatly improved light was obtainable. With regard to the Company's new "Kern" burner, this is much more efficient than the old "C" type, which gave a lower candle-power, was only made in one size, was detrimentally affected by an increase in the gas pressure, and required a chimney. It has already been shown that, as a light, the Welsbach is much better than the old form. Now as to cost, which in the majority of cases is the consideration. As an example, take a house having twenty ordinary gas-burners, each using five cubic feet of gas per hour and giving a 16 candle-power light. With these burners in use for 1,000 hours and with gas at 2s. 6d. per 1,000 cubic feet, you get a total of

£12 10s. If No. 0 Welsbach burners (consuming ¾ ft. of gas an hour) were substituted, the cost would drop down to £1 17s. 6d., besides which 25 per cent. more light would be obtained. When we come to compare it with electric light, it is found that with electricity at the low rate of 2d. per unit it would be nearly six times as expensive as a Welsbach light with gas at 2s. 6d. per 1,000 cubic feet. As a light, we do not think it equal in all respects to the electric light; but it is decidedly cheaper at the present moment. Whether it will be a decade hence is, of course, another matter. A great deal of attention has latterly been drawn to the increased application of the Welsbach incandescent light to public lighting, and when an actual examination is made it is surprising to note the extent to which it has been adopted. The burner best adapted for public lighting is the No. 4 new burner, which, with a gas consumption of four cubic feet an hour, gives a light of 100 candle-power. Without going into figures it may be mentioned that the same difference is found between the cost of street lighting by the Welsbach system and by electricity as when these two systems were compared with regard to indoor lighting. The electric arc lamp is at present in a state of imperfection, and may possibly be wholly supplanted in the future by something less complicated and spasmodic. The arc lights in the district of St. Pancras cost about £30 a year to maintain. It was first thought that the mantle was too fragile for outdoor use, but, where proper lanterns fitted with anti-vibrators are employed, this fear has proved groundless. Even in most exposed places, and where vibration is excessive, six mantles a year have been found to be ample, which (for the No. 4 burner) would amount to 4s. 6d. only. Our esteemed contemporary the "Lancet" says of the Welsbach system, after having made a special enquiry, that "the heat and carbonic acid produced by the combustion of this burner is one-half that of an ordinary gas burner, though the light given is more than three times as great." Enough has been said to show, and prove, the superiority on all sides of the Welsbach over the old systems, and its lower cost as compared with the electric light, and it would need no further proof that these merits were appreciated than the fact that the number of private and public users of the Welsbach mantles and burners increases daily.

The Bricklayers and Carpenters of Taunton have sent in a demand for an increase of a 1d. per hour in their wages, with the intimation that if their request is not complied with they will cease work on April 1st. The wages they now receive are 6d. per hour, and they ask for 7d.

EFFINGHAM HOUSE,
ARUNDEL STREET,
STRAND, W.C.

An Architectural Causerie.

"Primarily an Architect."

In a recent article on the work of Mr. C. F. A. Voysey in "The Furnisher," the writer—in a description of certain designs for decorative fabrics, wall-coverings and furniture—reminds his readers that Mr. Voysey is "primarily an architect." In the next sentence, however, he hastens to explain the views which this architect holds upon the scope of his calling, and those of us who are familiar with Mr. Voysey's work know how conscientiously he carries out these views down to the smallest detail in the smallest house. The fact, however, that it seems necessary to have to explain the particular opinions of a particular architect on the legitimate provinces of his art, is suggestive of thought and consideration. The dictionary definition of an architect is "one who plans and designs buildings and superintends their erection," whilst a decorator is described as "one who adorns or embellishes"; and this may fairly be considered to be the opinion of the "man in the street," should he trouble himself to express one on a subject of such little general interest. It is only upon the very special occasion when the "man in the street" wishes to build himself a house, or for his exceptional qualifications is hoisted into a position of trust and judgment on the building committee of some municipal building, that he begins to busy himself upon the duties of an architect and the limitations of the profession. The architect is naturally expected to be an omnipresent being, always on the work in progress, yet at the same time never away from his office—designing, drawing, and superintending the plans of the particular building in which the client is interested. It is also quite expected that for the munificent commission of five per cent. the architect shall be a sanitary specialist, a quantity surveyor, an engineer, electrician, and legal adviser. It is, however, absolutely outside an architect's province to suggest a scheme of decoration for the building he has built, or to design the furniture which is to be placed in it. Should such a suggestion be made, the client displays a feeling of intense distrust in the practical qualifications of the architect he has employed, and is dismayed to perceive the cloven hoof of the artist appearing beneath the inevitable frock-coat of the professional man. It is not the object of this article to lay down any particular code of rules setting forth what an architect should or should not undertake, but rather to suggest that it is as undesirable as it is difficult to draw any particular line of demarcation, such as a dictionary definition, between architecture and decoration.

Whilst one cannot agree with those who contend that an architect should invariably hand over his building to the decorator and furnisher to embellish, it is a mistake to insist upon an architect designing everything relative to the house. If he can do this—and one is delighted to find some architects who can—a homogeneity is arrived at between the architecture, decoration and furnishing which can be obtained in no other

way—it is the "ideal," but often it is not possible. There are many—far too many—good architects who are quite unable to furnish a colour scheme or design a sideboard, and it would be narrowing the circle indeed were we to exclude these from practicing their calling. Whilst, therefore, it is impossible to say where an architect should end (so much depends upon the individuality of the man himself), it is possible to say where the decorative artist—for there must be decorative artists—should begin. One need only glance down a few of the names which have animated decorative life in the last decade alone to recognise the primary importance of an architectural training before attempting decoration. Over such names as William Morris, J. D. Sedding, Philip Webb, H. Wilson, Baillie Scott and

form and treatment in the building which has to be decorated. The conclusion which a thoughtful study of the kindred nature of architecture and decoration brings us to is, that every architect should decorate and furnish his building, seeing that in this way one obtains the impression of one mind throughout the entire work. But whilst architects are year by year realising the necessity of studying decoration more than they have done in the past, we regret to notice no sign of a corresponding desire towards the study of architecture on the part of the decorative artist. This, in a very great measure, is the fault of the training the student receives in the great art schools, such as South Kensington and elsewhere. Hundreds of students, covered with diplomas and prizes, yearly proceed from these (presumably) centres of art

R.I.B.A. PUGIN STUDENTSHIP: MEDAL OF MERIT. STE. GILLES À CAEN.
DRAWN BY J. A. WOORE.

C. F. A. Voysey, to mention only a few, could be written "Primarily an Architect." The reason for the insistence of a knowledge of architecture is not difficult to understand. The simple laws of construction upon which all true building is based, the gradual development of "style" which from time to time fashions and forms such building to express the particular requirements of a particular period, form the alphabet of decoration. The artist who would lightly undertake to embellish an interior without being conversant with the simple laws of construction which animates the building is surely more than likely to introduce an entirely foreign element into the decorative scheme. Again, should the artist affect to despise a knowledge of "style," how is it possible for him to finish satisfactorily, for example, a "Georgian" building? It is useless to ignore the dominating influence of architectural

education utterly unfit to undertake the decoration of an ordinary drawingroom. Their complaint is, when they get no employment, that the architect has overstepped the rightful limits of his profession and intruded on their domain; but as a matter of fact architects are realising that the only satisfactory manner to finish a building is to do so themselves, and not to employ incompetent dreamers. It is not given to one man in a thousand to design a "Trocadero" frieze, but there is a real demand for decorators who have studied architectural style and are in sympathy with the building that needs embellishing. Such an one will always find encouragement and help from the architectural profession, but in proportion as this type ceases to exist, in the same proportion will the list be extended of those decorative artists who "primarily are architects."

H. S. M.

The Wayfarer on his Discovery.

AFTER paying several visits to architects of the younger generation, and making two or three secret calls at the Arts and Crafts in Regent Street, the Wayfarer came to the pleasant conclusion that there might really be something in this new discovery of his; that he had often thought the same thing about other discoveries seemed in no way to damp his present enthusiasm. It is true that he found the followers of this New Art movement were not so much bound together by ideas in common as by a wish to outdo one another in originality. A spirit of emulation was a strong characteristic of the school, and if the results at times seemed inadequate to the amount of thought and feeling given out in the production of some article for daily use, this detracted but little from his belief that here was a new school, quite unique in its peculiar way. It was always an easy matter to pick out an individual member of this band from among a crowd of architects, designers, and craftsmen, not because they wore soft hats or Liberty ties, but because a general air of intelligence, alertness, and enthusiasm distinguished them from their steady, sober, and perhaps rather more serious brothers in art. Mixing with the men belonging to this school revealed to the Wayfarer that they make use of the same terms, although their work is so different. A common phrase, often heard, is "The legitimate use of material"; they will also tell you that a wood moulding should be condemned if it is the least bit like a metal one, and so on. In referring to a building, you would be told that it was a simple, broad treatment, or that it was a trifle "Arty," or "not Arty," as the case might be. Peaky mouldings, filletless mouldings, columns with bases but without caps, hearts, diamonds, ellipses, darts, scoopings, trees, green paint, birds, beasts, fishes, potatoes on sticks stuck on ridges, and curiously wrought plates on the top of iron finials—these are a few of the amusing forms used in this New Art Movement. A heart shape is sometimes used the right way up and sometimes the wrong way up, the latter being thought a trifle more out of the common. Some favour diamonds, some circles, others again pin their faith to various treatments of the tree. Adverse criticism of all kinds, from the serious to the ridiculous, has been hurled at the heads of those who have been sarcastically described as "Nature architects," but, curiously enough, they still persist in designing hearts and other wonderful shapes which have not yet found a place in the architectural dictionaries. I am told, said the Wayfarer, that there is a remarkable example of a New Art building in one of the Glasgow thoroughfares. Across the façade and placed at certain intervals are groups of trees, birds, and fishes labelled "trees grow," "birds fly," and "fish swim." Could architecture be more graphic? cried the Wayfarer with enthusiasm, and what an object lesson for the city man in the street, who will soon forget if he is not careful that there are such things as trees, birds, fish, and that they grow, fly, and swim. A local paper, commenting on the architecture, suggested in a manner more frivolous than clever that another panel might be added with a group of donkeys labelled "donkeys bray." This, said the Wayfarer, with one of his rare and beautiful smiles, is a sample of the wit meted out to this New Art Movement, which, whatever its faults and shortcomings, seems to be an honest desire that "new design shall be founded on a strict consideration of the exact purpose to be fulfilled by the proposed object."

G. Ll. M.

On Reflection.

Strengthening the Housing Bill.

IN time of war domestic reform is apt to be neglected. It is therefore particularly gratifying that, in spite of the nation's preoccupation in South African affairs, there are increasing signs of a general desire to grapple with at least one old-standing and widespread evil, the utterly inadequate housing accommodation for the working classes. We make no apology for recurring to a question we have often discussed in these columns, for it is one in the solution of which builders and architects must necessarily take an important share. The Government has made some attempt—though a very feeble and inadequate attempt—to deal with the problem, and the immediate business before those who recognise its gravity and urgency is to strengthen the Government Bill so as to make it a real engine of reform. We note with satisfaction that the important conference held last week at the Memorial Hall, has come to precisely this conclusion; it accepts the Government Bill as an instalment, puts on record the reforms it considers represent the barest minimum of immediate requirements, and forthwith constitutes itself into a national committee to watch the Housing Bill, and to impress the need for the proposed reforms upon Parliament. A valuable object lesson in the powerlessness of local authorities in the present state of the law to cope effectively with the evils of overcrowding and insanitary housing is afforded by the great housing scheme of the L.C.C., the completion of which was celebrated last Saturday, when the Prince of Wales opened the last of the model blocks on the Boundary Street area. With the congratulations bestowed upon those who have engineered this great municipal enterprise we heartily agree. One of the worst slum areas in London has been completely swept away, clean and substantial dwellings, with ample breathing spaces, replace the filthy dilapidated hovels and narrow alleys of the old "Jago." But the old slum dwellers, where are they? Adding to the congestion of some neighbouring district, forming new slums, perhaps, but not to any considerable extent inhabiting the new blocks. When the old houses were destroyed their occupants had to shift for themselves; the Council had no power to build them homes in a suburban district and secure for them the advantages of cheap means of travel to and from their work; nor could they, when the new dwellings were completed, let them at rentals which the former inhabitants of the district could afford. The necessity for compensating the former owners, and for repaying the building loan within a period of sixty years made this impossible.

The Garden City Project.

ONE means of securing improved conditions of housing, of which more is likely to be heard in the near future, is the method advocated by the Garden City Association. From articles and correspondence which have already appeared in our columns most of our readers will be familiar with the general features of this project. It is proposed to establish a township on a suitable site which at present has no other than agricultural value; the community would be its own landlord, and obviously it would be possible under such conditions to supply healthy and ample dwellings at very low rentals. The scheme is one which, its promoters claim, is capable of being put into immediate operation and which involves no interference of any kind with "vested interests." If these are justifiable claims, and we think they are, is it too much to hope that it will not be long before there are found

a sufficient number of manufacturers and others bold enough and public spirited enough to establish the first "Garden City," and so prove by actual experiment whether or not this most attractive project (even its critics do not deny its attractiveness) is indeed capable of solving the problem of the housing of the working classes, as well as other scarcely less important social problems? The Association, which has been gradually and quietly increasing in numbers and influence since its inauguration last June, now makes an appeal for funds to enable it to obtain suitable offices and regular secretarial assistance, and to enlarge the scope of its work with a view to early practical steps in the work of building a "city of homes." The hon. treasurer is Mr. Alex. W. Payne, F.C.A., 70, Finsbury Pavement, London, E.C., and any of our readers who are interested in the project may obtain full information regarding it from Mr. E. Howard, 11, New Court, Carey Street, W.C., whose little book "To-morrow" first suggested the possibility of effective action on these lines.

Cheap Electricity.

WE announced some time ago that a company had been promoted for supplying electrical energy at a cheap rate throughout a great portion of South Wales. The Bill dealing with the scheme was, together with three other similar Bills relating to Lancashire, Tyneside, and Durham, read a second time in the House of Commons on Thursday. The House has thus changed its attitude towards private electrical corporations, for last session it refused, by a considerable majority, to read for a second time a similar Bill affecting a large manufacturing area in Nottingham and South Yorkshire. The main objection raised has been that the wholesale distribution of current by private companies was "a direct attack upon the rights, privileges, and duties of municipal corporations," and "would practically set aside the existing law which adequately protects corporations in the exercise of the duties which they have to perform." These duties have not, however, been fully performed, and this is one reason why our adaptation of electricity to commercial ends has been so lamentably behind foreign countries. To show that these new Bills are tending to a right end—the supply of current at a rate cheap enough to allow it to be extensively and largely used—let us consider the scheme for South Wales. To put the matter briefly, it is proposed that generating stations shall be erected practically at the mouth of the coal pits at Neath, Pontypridd and Pontypool, and that mains shall be laid at the side of the railways over the whole county of Glamorgan and the industrial part of Monmouthshire. The area so covered would be more than a thousand square miles, and is crowded with collieries, works, and factories. At the present moment only sixteen and a half square miles of this area have a public electric supply, and the average charge is about 5d. per unit; whereas the new company would not be allowed to charge more than 2d., and "it is probable the actual charge will be much less." Putting another comparison, the promoters say they will supply current at between £4 and £10 per horse-power per annum; the present cost ranges between £15 and £30. No exclusive powers are sought, and the Bill provides that no retail consumer shall be supplied without the consent of the local authority; and, in addition, the local authority may, at the end of forty-two years, purchase so much of the undertaking as is in its district at a fair market value. It is to be hoped that the Bills will be passed and a new era started, bringing down the price of electrical energy so that its use may be something akin to that which obtains in America, where the existence of large electric power plants alone makes cheap electricity possible.

JOHANNESBURG: BEFORE AND AFTER THE WAR.*

From an Architect's Point of View.

By JOHN BEGG.

THERE is a large amount of glamour connected with the idea of being in a new country, but I may say I needed it all to reconcile me to settling down in Johannesburg. I was not so foolish as to expect things to be done as well as at home, but at the same time I was scarcely so wise or so well-informed as to expect things to be quite as bad as I found them in the building trade. Take ordinary construction alone. I found it was the universal practice to use "imported" Swedish and American doors and windows in even the better class of houses. I found that plaster ceilings were almost non-existent and that the never-failing substitute was matchboarding—wretched spruce matchboarding 3 in. thick, full of cracks and shakes, and knots that did not stop short of being both "large" and "loose." I found that in timber generally the best the market could provide was inferior to our seconds or even thirds, and was all very expensive. Bricklayers' materials provided a case nearly as bad. The ordinary brick, called "stock"—but inaptly named if compared with that excellent article the average London stock—was a miserable ill-shaped lump that you could generally break with your fingers. And they actually had an inferior quality, well named "slops," which was a positive outrage on the unfortunate buyer. Very good facing bricks were to be obtained, but at what a cost, and it was one chance to ten that they would bond in with any other brick, so little did brickmakers understand the use of a uniform gauge. The price of cement was almost prohibitive. Lime was to be got in any quantity, but whether it was owing to the grinding, or to any adulteration, it could seldom be relied upon to set really well. As a substitute, a substance called by the Dutch name of "dagga" was much used in brick buildings of one storey. This is really nothing more than mud, the ordinary clayey soil of the country, screened from pebbles and large lumps and mixed with water to the desired consistency. This same "dagga" was the universal material for internal plastering in all except the very best work, and a wonderfully good plaster it makes. It can be put on with extraordinary rapidity, and is quite durable if you protect it with a good stout wallpaper and keep damp away from it. Then when one comes to the roof the architect has no choice, except between one gauge of corrugated galvanised iron and another. This material, which only a few years back was the one material for our walls as well, though it has been almost entirely ousted by brick, still retained its place on the roofs of Johannesburg. You may do what you will with corrugated iron, you may paint it red or green, or in stripes, or leave it for the dust to settle on and tone down its rawness a little, still it remains the emblem *par excellence* of naked and unashamed gimcracking. All this will give you some idea of what the architect has to depend on in the shape of materials. There is one material among so many that are bad to which I must give a tribute of unqualified praise; that is the excellent building stone which is quarried near Boksburg, at Pretoria, and just across the border of the Free State. But, as with everything else in that land of many limitations, the use of this is limited on account of the almost prohibitive cost of working it and bringing it to town by rail. An interesting experiment has recently been made in the manufacture of "Owen's Artificial Stone," such as is being made in the neighbourhood of Bathgate, Edinburgh. When this experiment was mooted, I was in hopes that a material was about to be produced that would enable one to discard plaster as a means of external adornment (and that at little more

than the cost of plaster), for Owen's stone, when properly used, is not an artificial stone in the ordinary sense, but a composition which can be cut, dressed and carved while comparatively soft, hardening afterwards on exposure. I cannot say that my hopes were fulfilled, for the manufacture never progressed much beyond the experimental stage, and the stone had never been produced in sufficient quantity to enable the makers to place it on the market at a sufficiently low price. So much for materials; I will now tell you something of

Johannesburg Building Construction,

and to do this I think I cannot do better than describe the erection from the foundations upwards, as if I were conducting an elementary construction class, of an average cottage—which, by the way, would be called a house out there, and would realise for its owner the rent of a mansion in Edinburgh. When the positions of the various walls have been set

this is a luxury only to be thought of in the best class of building. When the sills are set (they consist generally of one course of brick on edge) and the window-frames are placed, away we go up towards the wall-head, with perhaps one more course of hoop-iron in the partitions. The wall-plate will consist of a timber 1½ in. by 4½ in., tied down to the brick-work with hoop-iron straps; and then we are ready for the roof. In the meantime the carpenters will have been getting ready the roof trusses, of 4½ in. by 1½ in. timbers, halved at the apex, and secured to collars, ties and struts of the same scantlings fixed with 4 in. French nails clinched. These trusses are placed about 5 ft. 6 in. apart; on them are nailed the purlins (say about 4 ft. apart), of 3 in. by 2½ in. scantlings, and then the galvanised corrugated iron (24 gauge) goes on wholesale, with a din as of boiler-making. The ridges are finished with 18 in. galvanised ridging, the valleys with the same inverted, and the eaves with a piece of

THE MARKET SQUARE, JOHANNESBURG. DRAWN BY F. L. EMANUEL.

out on the ground, the bottoms are not dug out or trenched, but merely levelled and rammed. Then the masons start, and build what are called the foundations. These consist of rough rubble walls, 15 in. to 18 in. thick, in mud mortar, and they carry the structure up to the underside of the ground floor wall-plates. Sleeper walls of the same material are also built. Next follows a perfunctory damp-course of tar mixed with sand, and down goes a noble plate of 3 in. by 1½ in. A base course of one course flat and one on edge being run round the outside, you have the floor line marked. Ground floor joists 4½ in. by 1½ in., 15 in. to 18 in. apart, are considered sufficient to span 5 ft. 6 in. or thereabouts. Now, having placed the door-frames in position on their slate thresholds, we proceed gaily up to the level of the underside of the window sills with 9 in. brickwork (in mud mortar) for the external walls, and 4½ in. brickwork for partitions. We now treat ourselves to a course of hoop-iron all round, in external walls and partitions alike, and

6 in. skirting board turned upside down as a fascia, to which is fixed a 5 in. zinc ogee-moulded gutter. Now, while the plasterer is slushing on mud inside by the square rood, the bricklayer will take the opportunity of covering multitudes of his deficiencies outside with a coat of red distemper, after raking back the mud from the joints and pointing with lime mortar, finishing by sticking on neat lines of black and white pointing, according to the taste of the architect. The effect is wonderfully smart, and, to the Philistine soul at any rate, satisfactory—until the first shower of rain comes. But by that time the house is probably let on lease or sold; so why should it retain its freshness any longer?

Our house is now ready for the flooring, and this in no way differs from that dear to the heart of the jerry-builder at home—6 in. by 3 in. grooved and tongued flooring, not secret nailed. The skirtings present no difficulty, for no one would think of specifying them to be grooved to the floor; nor do the ceilings present any difficulty, except that you must place inter-

* A paper read before the Edinburgh Architectural Society on February 28th, 1900.

mediate ceiling joists between the ties of 3in. by 2in. to bring down to 2ft. 9in. the spaces which the matchboarding must bridge. The cornices will possibly be of 4in. wood mouldings, or 6in. for very important rooms, mitred and nailed to the ceiling boarding. If the house is desired to be really something superior, the dining and drawing rooms will have the ceiling boards covered with calico, well stretched and tacked, and this again covered with a ceiling paper, or with Anaglypta, or Lignomur, or some such material; or, possibly, in the case of very superior work indeed, instead of boards, calico and paper, with sheets of stamped steel of the thickness of brown paper, imported from America and much admired.

Now, after a few days spent on sawing up and planting on stock mouldings, such as architraves, &c., fitting window sashes, doors, locks, and windows, the work is handed over to the paperhangers and painters, who effect on it their customary marvel of transformation.

That is how a house was built in Johannesburg before the war. An ingenious architect might show his individuality by boldly refusing to colour and tuck-point the brickwork by flying in the face of public opinion and substituting plain colour for good, sensible, handsome graining by his selection of wallpapers, &c., and thereby might secure some satisfaction to himself; but his clients would have been better pleased had he spent his time in discovering how to squeeze in another room, so enabling a couple of pounds per month to be added to the rent. In short, there was no architect in Johannesburg who would think of worrying his head about whether his calling was a profession or an art, knowing well that it was *neither*, though he might admit it is open to question whether it were a *business* or a *trade*. There can be no doubt that the average quality of an architect's practice in Johannesburg was very low indeed, and the reasons for this are not far to seek. In setting these before you I hope to give you some idea of the

Adverse Conditions

with which we have had to contend. As these reasons are all more or less connected with the unsettled state of the country—apart merely from its being a *new* country—I am afraid I shall have a hard task to avoid entering the field of political controversy.

I would classify these adverse conditions thus:—(1) The unsatisfactory political state of the country; (2) the enormous cost of labour and materials; (3) the climate; (4) the want of culture on the part of the people; and (5) the unsatisfactory sanitary conditions.

I am aware that this classification is imperfect, for four of the above conditions are more or less referable to the first; but I want, as far as possible, and as soon as possible, by attacking and dismissing the first condition, to eliminate the political element from this paper. The Uitlanders of Johannesburg found little or no inducements to regard the place as their home. They were debarred from having any voice in the management of the country; they were treated with incivility by officials, alike in the Government, railway, post-office and police services, and by the latter even with violence. They found it next to impossible to obtain justice in the Courts. They were taxed exorbitantly. They could hardly get decent education for their children. Moreover, all these grievances showed signs of steadily becoming aggravated, instead of diminishing, as years went on, all attempts to obtain reform from the Government being met with refusal and increased burdens and disabilities. What wonder is it that they should all look forward to leaving a country where they were so unwelcome? Though few in these later days could hope to make a fortune on which to retire, or even a modest competency, still there was hardly an Uitlander who did not secretly desire to go home some day for good, and who did not inwardly cherish a vague undefined hope of being able to do so. Hence few cared what sort of house they lived in. Even the very wealthy would seldom spend money on building themselves houses any better than just good enough

to "rub along" in. Again, all this led to an entire lack of public spirit. There were few public men to endow public institutions or enrich the town with public gifts. I know of no building in Johannesburg that could be called in any sense a public building, with the single exception, perhaps, of the hospital. The very town council hired its premises from an enterprising speculative builder. So that the town became one of rent-producing buildings entirely. Finance, and often most sordid cheese-paring finance, dragged its slimy tail over every building from one end of the town to the other. Just think what the architectural traditions of Edinburgh would be if the city were robbed of her public buildings—her university, her free library, her churches, her galleries and museums, her monuments, and the sumptuous homes of her wealthier citizens—and were left in the hands of her speculative builders! Then how much worse was Johannesburg's case when to have money in house property was regarded as such an insecure investment that men were seldom satisfied with a less return for capital invested than from twelve to twenty per cent., and frequently could get very much more. So uncertain was the future of the country, its prosperity so subject to unexpected checks, that they must needs require the return of their money within a correspondingly small number of years. Thus the speculative builder—that is, practically, the only builder—did not care to give his productions even the small modicum of substantiality to which he condescends here, and Johannesburg jerry-building was such as to give points to jerry-building anywhere in the whole world. You must admit that the case seems pretty hopeless for good architecture. In a country whose commercial history is one of sudden wild "booms," alternating with acute panic "slumps," you can hardly expect to find much in the way of lasting memorials to human industry. It has been boom and slump, slump and boom, ever since Johannesburg grew up out of the veldt, some thirteen or fourteen years ago; and the majority of these crisis times are mainly traceable to the political conditions. Of course, this is not entirely so. You cannot prevent booms and slumps in new countries; the case of Melbourne shows that; so we could hardly have escaped Johannesburg's first big boom soon after it began to attract the attention of European investors and the inevitable reaction which followed. But the exceedingly unstable, passionately retrogressive policy of the Pretoria Government has prevented the Transvaal from settling down, and its markets from, as it were, finding their own level. I maintain that nowhere have the conditions been such as to justify a more steady level of prosperity than on the Witwatersrand—certainly on no goldfield in the whole world. The Rand reefs have this enviable peculiarity that they are so even in quality, and follow with so little deviation definite ascertained laws, that, given a certain area of gold-bearing property to be worked, you can, after a trial bore or two and an assay or two, estimate both the yield from the entire area and the cost of production, with such accuracy as to be able to approximate actual working and the estimates, to within a very narrow margin of error. So we should have had a right to expect and find long before this that the markets would have found their level, and the only thing that has prevented this happening, and which has occasioned the distressing see-saw that ever kept one from knowing for more than a few months at a stretch "where he are," the only thing has been that policy on the part of the Boer Government arising from the now frankly-avowed Dutch ambition to drive the British out of South Africa, the same that has directly led to the present deplorable war.

But to this unsavoury subject there is no end. I have said as much as is excusable by its application to architecture, and so will pass on to the second of my adverse conditions—the enormous cost of labour and materials. Here, again, we are confronted with the reactionary policy of the Government. It is only to be expected that materials would be dear, but they need not be so dear; Government need not have created a monopoly in

pressed bricks, or in cement; but, most of all, the exorbitant freights which are due to the railway monopoly need not have been such a ruinous item in the cost of materials. Again, had the country been such as a white man could live in contentedly, skilled labour would not have been so dear, for we should not have had to depend on mere birds of passage, and a regular working-class would have settled down in the country. And once more it is directly chargeable to the Boers' hostile attitude towards the Kaffirs that native or unskilled labour cost in the Transvaal double what it did in any other part of South Africa.

A comparison between the prices of a few leading "lines" there and at home will be interesting. I shall give you the Johannesburg prices, and you can supply what would be those to correspond in Edinburgh:—9in. by 3in. deals cost 7d. to 8d. per running foot, all smaller timber in proportion, plus sawing; stock bricks cost about £3 to £4 per 1,000; pressed bricks, about £5 to £7 per 1,000; freestone, ashlar, dressed and delivered ready for building, cost 10s. to 10s. 6d. per cubic foot; ½in. flooring cost 4d. to 4½d. per square foot, and 12s. 6d. per square for labour in laying was an ordinary piecework price; bricklayers' wages were 22s. 6d. per day; carpenters, painters, and plumbers' wages were 20s. per day; Kaffir labourers earned about £1 per week.

To show you how the cost of goods ordered from home was affected—such goods as grates, pavement lights, door and window furniture, locks, &c.—I have before me an instance; and in no way an abnormal one. The goods, packed and delivered free on board at the home port of embarkation, cost £76 13s. 3d. Shipping freight, dock dues, railway rates, duty and other charges, had brought the price up to £158 10s. 3d. by the time the goods reached Johannesburg; and to this has to be added the agent's commission, so that the increase in the price of goods imported from home is very greatly more than 100 per cent. of the original cost. Roughly speaking, building in Johannesburg costs twice what it does in London for the same class of work. But perhaps you will say that that is no hardship to an architect, and will ask me to think of the consolation of five per cent. on the larger amount. But an architect has to live, and living also costs double—so there is that argument disposed of. And as a matter of fact people did not spend double on their buildings. The greater cost of building only served to accentuate what I have mentioned before, the tendency of people to build in as gimerack a manner as they could. As the price of work goes up, the cost of the building does not. But the quality of work goes down, leaving the cost of the building about the same. Buildings per cubic foot cost much what they do at home, only if you were to examine them you would find the walls thinner, the timbers lighter and wider apart, all the dainty et ceteras that go to make our buildings complete left out wholesale, and an infinitely poorer quality of work employed generally.

I have set down the climate as the third of my adverse conditions with which architects have to contend, and you will no doubt be surprised. That what is so widely acknowledged to be the finest climate in the world should have anything but a good influence on architecture does seem a far-fetched theory. I may remark in passing that, having experienced several climates, I think it quite an argumental point whether the finest climate in the world may not be found on our own Islands; but that, by the way. I will admit that the climate of the Transvaal may truly be considered as constituting a negative condition, which only becomes unfavourable in conjunction with other unfavourable conditions. It might be quite the reverse—and who knows but in the future it may be—but of that more anon, when I come to the part of my paper dealing with the future. As things have been in the past, the very fineness of the climate has aided and abetted the building of rickety houses, which in this country would have been blown down, or washed away, or shattered by frost ere they had stood a couple of years. There are none of our

soaking, wearing rains out there; none of our combinations of heat and frost so destructive to buildings—for frost occurs only at night, and that in the dry season of the year when you may not see a cloud in the sky for six months at a stretch.

The fourth drawback is what I have called the want of culture on the part of the people. This is inevitable in a new country, and still more inevitable in an unsettled one. Therefore, I must not be misunderstood to cast any slur on the Uitlanders of the Transvaal. Culture proceeds, as a rule, from the leisured and moneyed classes, and thence spreads downwards in the social scale. In the case of Johannesburg there was no leisured class. Those who had leisure and money preferred to spend both in Europe. Then the cultured professional classes—except, perhaps, in the case of the engineering professions—necessarily bore a much smaller proportion to the bulk of the community who were drawn mainly from the busy commercial classes. Had these any inclination to spend what time they could snatch from the cares of business in improving themselves intellectually, there were no examples to study, no museums or galleries, and but few books and lectures. So unless an architect found himself the happy possessor of a most exceptional client, to translate his client's ideas into even ordinary grammatical building was like that old problem in the earliest known examination in building construction—to make bricks without straw.

As to my fifth drawback, I suffered from the want of drains. When you hear anyone say we should be perfectly healthy if we had no drains, don't believe him. I have lived three years beside the so-called "bucket system," and I think I know. The necessity of providing that loathsome alley—called a "sanitary" passage, but, in fact, both insanitary and unsavoury—opening on to the street-front of every building was only a minor disability. The want of drains ruled with harsh unbending sway over all planning, and stultified the best efforts of the architect to bring his house, club, hotel, or chambers-block up to modern ideas of comfort.

I must here close my sketch of Johannesburg before the war. What am I to say of Johannesburg after the war? I confess I allowed myself, in composing the title of this paper, to indulge in somewhat of the spirit that animates the ingenious authors of the catch-halfpenny headlines to the evening papers when I put down the words "and after." I knew that many would be keen to have a hint of what is likely to follow the war, and that many young architects would be so from their desire to know what Johannesburg is likely to be as a field for the modestly aspiring in our profession. Well, I of all people find it to my interest to know that—yet I candidly confess I do not know. I do not by any means regret my past experience out there, but I have no idea whether I shall go out again myself or not. Uncertainty has become the acknowledged characteristic of all South African ventures, and so I cannot say to one who might go out to push his fortune, "Go, and you will never regret it." I can only give a few pros and cons for you to weigh in your own minds, a few heads and tails to toss up, each enquirer for himself, and see which comes down uppermost.

Architectural Practice after the War: Pros and Cons.

Pro No. 1.—There can be no doubt we mean to push this war to a successful issue (and that is equivalent to saying that we will push it to a successful issue) and to give the Trans-

vaal a just and a settled government. Under this most of the drawbacks I have mentioned are certain to disappear. Public spirit will be fostered, and, as a natural consequence, all manner of public buildings will fall to the lot of architects. Culture will increase, and with it the desire for good work. Security will be so vastly improved as to warrant the spending of money on more substantial buildings. Johannesburg will speedily have a proper drainage system. The climate under improved conditions will become an incentive rather than a hindrance to good architecture, and many individual treatments (signs of which are seen in the verandah or "stoeps," colonnades, heavy eaves,

new buildings they will not rather have to content themselves with patching the old garments. *Pro No. 2.*—I have felt for a year back that the country has been spoiling for a boom. A boom is bound to follow the successful finish of this war. *Con. No. 2.*—But booms are always followed by slumps. *Pro No. 3.*—Granted. Nevertheless, apart from that there is bound to be such an influx of fresh European capital that hundreds of fresh enterprises will be set on foot, and hundreds of new buildings required. And I spoke of "patching the old garment." This in many cases will mean much work for architects. The greater part of Johannesburg and Pretoria may need rebuilding

THE CASTLE BREWERY, JOHANNESBURG. DRAWN BY F. L. EMANUEL

and cornices, and such sun-protecting features) will develop from the open-air life of the people. In short, the war may be expected to remove all that has been keeping not only the Transvaal but all South Africa back for years. *Con. No. 1.*—But the country will have to bear the enormous expense of this war, and of maintaining for an indefinite number of years an army of occupation of, perhaps, 40,000 men. Exorbitant taxation has been one of the Uitlander's greatest grievances; but it will be safe to say this can at least be no less for many years to come. And for years to come trade will feel the effects of the dislocation that this war has caused. It is a question whether instead of the towns clothing themselves with

at the end of the war. *Con. No. 3.*—But there will be plenty of architects to do the work. The profession was far more overcrowded in Johannesburg before the war than it is even in Edinburgh, and the fresh inrush of population that will follow a settlement may be fairly expected to bring with it its own proportion of architects. *Pro No. 4.*—A young man has always a better chance in a new country which is going ahead. *Con. No. 4.*—Yes, a young man, but not a young man without influence. The young have chances in a young country that they have not in an old; but old or young, influence is even more necessary than at home. This is a circumstance which is often lost sight

HOUSING.

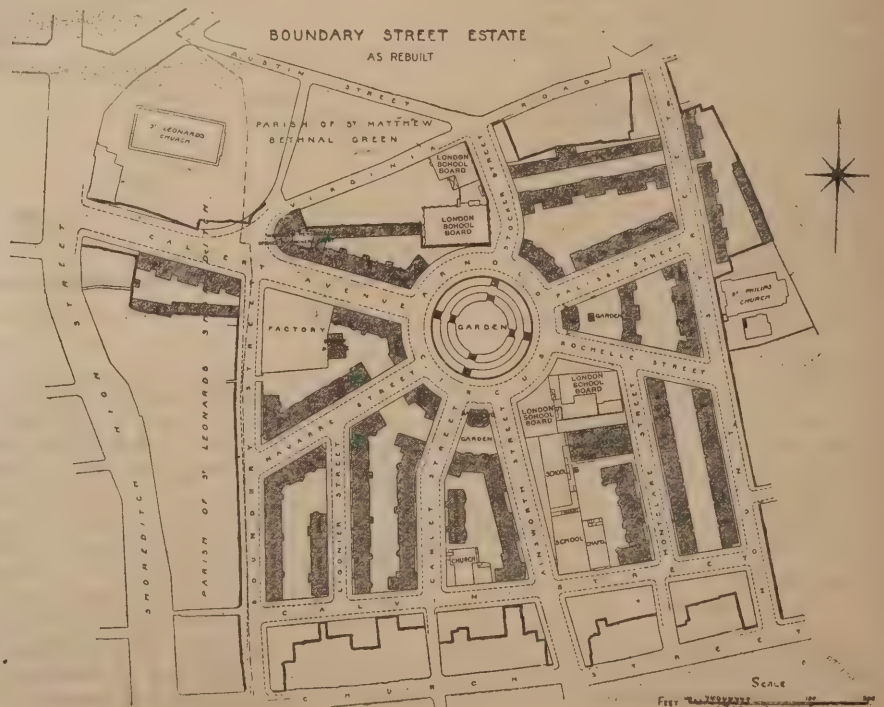

Completion of a Great Scheme.

of, but it is certainly the case, and the reason for it is easy to understand. In Johannesburg, in common, I suppose, with most mushroom places, the population contains such a large proportion of adventurers, black-legs, failures, and refugees from elsewhere, that the business principle of distrusting everybody is carried to excess. This principle inculcates that every man whom you know nothing about is a blackleg; hence the unknown man, however charming his manners or taking his address, finds it difficult to make a beginning. The mere ordinary letter of introduction is not enough. These, from however influential a source, are almost useless. The introduction that is to be of any practical service to a man going to Johannesburg must have something special about it. It must arise from some particular circumstances or it counts for little. *Pro No. 5.*—There is every reason to expect that Johannesburg in the future will contain sufficient inducements to lead people in prosperous circumstances to make their homes there. The climate is splendid; the country beautiful. The causes that led such people to make their homes in England, namely, the unsettled state of the country and the scarcity of means of education for their children, will be removed. These people will want good houses to live in—hence plenty of work for architects. *Con. No. 5.*—But it is only reasonable to expect in the future that, though the rank and file will be more prosperous, there will be no such crop of millionaires raised as of old. Under the flag that is likely to wave at Pretoria it is the greatest good to the greatest number that is always fostered, not the rapid enriching of the few. Moreover, Johannesburg's rich men have already all become domiciled in Europe, and it is a question whether they will not continue to live there, contenting themselves with being represented as heretofore by agents. *Pro No. 6.*—The Transvaal's glorious climate is a prime inducement to anyone to take up his abode in Johannesburg. The exhilaration of breathing that champagne-like mountain air must be experienced to be understood. To wake up morning after morning for half a year to days of unbroken sunshine; to smoke the pipe of peace of an afternoon on a cool, shady verandah and look at the sparkling landscape; to smoke the pipe of peace of an evening on the same verandah and look out on the African moonlight, so bright that you can read by it; to know that however hot the noon the night that follows will be cool and one's sleep refreshing; all these things give a zest to existence that even the Boer's hostility and trickery are powerless to destroy. I will not weaken that pro by a single contra.

ON Saturday last H.R.H. the Prince of Wales opened the last block of dwellings on the Boundary Street Area, Bethnal Green, N.E., the reconstruction of which was the first large scheme undertaken by the London County Council under part 1 of the Housing of the Working Classes Act, 1890. The royal visitors were received by Lord Welby, chairman of the Council, and the Prince expressed his great satisfaction with the work that had been done, giving in the course of his speech several personal reminiscences of the Royal Commission of 1884 on the housing of the working classes.

The Boundary Street area lies to the east of High Street, Shoreditch, and north of the Bethnal Green Road, and is about fifteen acres in extent. It is square in shape, and is bounded on the north by Virginia Road (see plans), on the east by Mount Street, on the south by Old Nichol Street (since renamed

Calvin Street), and on the west by Boundary Street, from which its name is taken. To go no further back in the history of London than some 300 years, the whole of the site of this area formed part of the garden of the nunnery of St. John the Baptist, Holywell. Upon the maps of London of two hundred years ago we still find the area unbuilt upon, but between that time and the beginning of the present century the land began to be covered with buildings. It is about this time that Old Nichol Street makes its appearance, followed almost immediately by the streets parallel to it—New Nichol Street, Half Nichol Street, Vincent Street, and Mead Street. These latter streets are said to have been constructed about the time of Nelson's great victories, and to have been named after his admirals. That certainly seems probable; but, at any rate, the great majority of the houses and streets upon the area appear to have been constructed at or about that time. The houses, therefore, were at the time of their demolition in 1893-5 somewhat less than a century old. Besides the streets already mentioned, however, there existed all over the area, but more especially off Old Nichol Street (which, together with its parallel streets up to Mead Street, was known as "the Nichol") small courts, entered under the houses and built generally over what had been the gardens or yards of the original houses. It may here be remarked that "the Nichol" is identical with "the Jago" so vividly and ably described by Mr. Arthur Morrison in his book "A Child of the Jago." Whatever might have been the original character of the occupiers of these narrow streets and courts, there is no doubt that by the eighties "the Nichol" had become one of the worst areas in the east of London. In Old Nichol Street alone there dwelt at one time no fewer than sixty-four ticket-of-leave men; while morality was literally at its lowest ebb. The work done by the present vicar of Holy Trinity, the Rev. A. O. Jay, ought at this juncture to be noted with praise and admiration, for he did much to ameliorate the existing conditions. In the building of these wretched hovels, speaking generally, no mortar was used, but in lieu thereof a curious substance known as "billy-sweet." It is one of the properties of this substance that it never dries. Add to this that the houses were, in the majority of instances, so constructed that the ground floors were from 12in. to 18in. below the street level; that the widest street was barely 28ft. across; that no house possessed such a thing as a front door; that no repairs were ever done to the houses; that what back yards had ever existed had nearly all been roofed in and occupied as

further houses; and you may have a bare idea of the state of things which caused the death-rate in this particular neighbourhood to mount up to over 40 per 1,000 in 1889, a rate nearly twice as great as that in the parish of Bethnal Green, and the practical meaning of which is, that out of every twenty-five living persons on the area one at least was sure of death within the year.

It was this state of things that the Council, advised by its medical officer, Mr. Shirley F. Murphy, and acting on the representations of the medical officers of the parishes of Bethnal Green and Shoreditch (Dr. G. Paddock Bate and Dr. W. H. Sutton), decided in 1890 to step in and remedy by an exercise of its powers under the Housing Act, then just passed.

Shortly, the scheme, which was commenced towards the end of 1891, was to demolish the old houses bit by bit; to form wide new streets on the area upon an entirely new principle, and to construct new blocks of flats for the reaccommodation of as many persons as was consistent with a due regard to health and sanitation. The net cost of acquiring and clearing away all the old insanitary houses and constructing the new streets, paving them with asphalt, will probably amount to £270,000. The area is approached by an avenue 60ft. wide, leading direct from Shoreditch High Street to a central open space, as shown on the plan. Streets 50ft. wide, planted with trees, radiate from this centre to the limits of the area, and these are also connected with the streets bounding the area by branch streets 40ft. wide. The four streets bounding the area have been widened to 40ft. The cost of forming, paving, and sewerage these streets amounted to nearly £50,000. In addition to a church, there existed two board schools, a ragged school, and a large tin factory. These are left untouched. Upon the building sites formed by these streets, blocks of dwellings have been so arranged that the living room of every tenement receives the benefit of sunlight at some time during the day. In all, twenty-three blocks of dwellings have been erected. Of these, twenty-one are from designs prepared by the council's staff under the direction of Mr. T. Blashill, the late superintending architect to the Council, and approved by the Housing Committee, and the remaining two are from designs prepared by Mr. Rowland Plumbé. These provide accommodation for 5,380 persons in fifteen flats of one room, 533 of two rooms, 388 of three rooms, ninety-eight of four rooms, seven of five rooms, and three of six rooms. There are thus 925 tenements now in lieu of the 730 houses formerly existing on the area. The cost of the buildings amounts to nearly £270,000, in addition to the cost of purchasing the properties and the value of the land, amounting to about £333,000. These figures include the provision of cottage dwellings for some 144 persons at Goldsmith Row, a little distance from the actual area, built in order to afford house-room for some of those displaced while the other new dwellings were being erected. Besides the actual dwellings, the estate comprises a central laundry (see inset sheet) fitted with all the latest mechanical conveniences for washing and drying clothes, and containing baths and two good-sized club-rooms, which latter are available for the use of the tenants of the estate for social meetings, concerts, &c. Baths fitted with hot and cold supply of water are also provided in one of the blocks of dwellings. Between the various blocks of buildings are provided large paved yards, which form playgrounds for the children, and one of these is laid out as an ornamental garden. The central open space is circular in shape, and is formed in terraces and provided with seats, shrubs being planted on its slopes. Seventy-seven workshops and eighteen shops have also been built, the former for the use of the occupants of the buildings, the latter including all buildings necessary for a baker's establishment. In order that the estate may be completely managed, and repairs immediately necessary looked to on the spot, a central workshop is also provided, fitted for the execution of all such works. The buildings have been named in a series, after the various towns to be met with in a journey up the Thames, so that

there are, on the north-eastern portion of the area, Streatley, Sunbury, Chertsey, Taplow, Hurley, Culham, and Sonning Buildings; on the south-eastern portion, Henley, Walton, Cookham, Sandford, Molesey, and Clifton Buildings; on the south-western portion, Ilfley, Hedsor, Laleham, Benson, and Abingdon Buildings; and on the north-western portion, Wargrave, Shiplake, Marlow, and Cleeve Buildings. The Falcon Brass Works, Limited, of Holland Street, S.E., supplied their "Flood" pattern syphon waste-preventing cisterns to the tenements.

In this scheme, as in others promoted by the Council, the aim has been that the dwellings, while let at rents not exceeding those ruling in the neighbourhood, shall be so designed as to be self-supporting (the average rent works out at about 3s. per room per week, two rooms 5s. 6d. to 8s., three rooms 7s. 6d. to 9s. 6d., four rooms 9s. to 12s. 6d.). That is to say the rents fixed on that basis shall be sufficient to pay all outgoings, including interest on the capital expended on land (at its value for housing purposes) and buildings, and the provision of a sinking fund for the repayment of such capital within a period of sixty years.

It may also be of interest to briefly set forth what the Council has done and is doing for the better housing of the working classes of London generally. In the clearance only of insanitary areas it is spending £1,114,800. For this sum thirty-five acres of old, dilapidated and insanitary dwellings will be demolished, and 16,160 persons will be displaced; 1,908 tenements, affording accommodation for 10,060 persons, are already completed and occupied; 1,190 tenements, affording accommodation for 5,900 persons, are in course of construction; and in addition plans are being prepared by the superintending architect of the Council, Mr. W. E. Riley, for 3,718 tenements. These will afford accommodation for 19,990 persons, and the total cost, including the value of the land, is estimated at £1,008,799. It will thus be seen that the Council has provided and is providing accommodation in 6,816 tenements for 35,950 persons, at a total outlay of £1,945,277. Of these, 145 tenements will contain one room, 3,271 two rooms, 3,160 three rooms, 229 four rooms, 8 five rooms, and 3 six rooms. Further, 5,251 persons will be accommodated on areas about to be cleared, but the cost of this work has not yet been estimated.

It is of course hard to realise from a bare statement of the figures what is meant by the work that they indicate, but some idea of its extent may be gathered from the fact that the Council is engaged in building operations which, if conducted at one spot, would result in the formation of a town of nearly 36,000 inhabitants; that is, of the size of Macclesfield, the well-known manufacturing town in Cheshire. This result will be achieved at the expenditure of a sum of nearly two millions sterling.

Additions to the Drill Hall, Dundee, have now been completed. The buildings occupy the full width of Parker Square. On the first floor is a largely extended armoury, three officers' rooms and the adjutant's headquarters, and on the second floor are several large rooms and the sergeants' headquarters.

The late Mr. John Wade, of Barnsley.—The funeral of Mr. John Wade, architect and surveyor, of Barnsley, took place on February 28th. Mr. Wade came to Barnsley as assistant to the late Mr. George Senior, with whom, after two years, he became partner, the firm continuing until 1862, when it was dissolved by mutual consent, and deceased carried on the practice. In 1854 he became surveyor to the local board, and he held that office at the incorporation, and defined the boundaries of the wards as they at present exist. In September, 1868, he entered into partnership with Mr. Benjamin Turner, but continued to act as surveyor to the Corporation until about 1872, when he resigned on the Council wishing him to devote the whole of his time to the duties of the office.

WORKMEN'S COMPENSATION.

THE case of *Cass v. Butler* was heard by the Court of Appeal on February 24th last. This was an appeal from the decision of Judge Greenhow, the Leeds County Court judge, in proceedings to assess compensation under the Workmen's Compensation Act, 1897. The respondent was the widow of Henry Cass, who at the time of the accident was a painter in the employment of the appellant. It appeared that a builder and contractor named Isaac Gould had entered into a contract to build and complete an electrical station. Gould then entered into a sub-contract with the appellant, who was a painter, that the latter should do the whole of the painting work of the building. The building was being constructed by means of a scaffolding, and was over 30ft. in height. On June 17th, 1899, Cass was engaged in painting the iron girders of the roof, and was standing on the scaffolding belonging to Gould, which was used in the erection of the building. While Cass and another man named Crowther, also in the employment of the appellant, were so engaged, a plank broke and they fell and were killed. It was admitted that this new building was being painted for the first time. The County Court judge held that the appellant was an "undertaker" within the meaning of the Act, and that the painting of the new building was "construction," and he made an award of £235 6s. in favour of the respondent. It was contended for the appellant that he was not an "undertaker" within the meaning of the Act. The contractor, Gould, was the undertaker, as he was "undertaking the construction" of the building within the definition of "undertakers" in section 7, sub-section 2. A sub-contractor was not an undertaker. Section 4 clearly showed that the contractor was liable as the undertaker, though he might be entitled to be indemnified by the sub-contractor. This was not like the case of *Mason v. A. R. Dean, Limited* (see page 63 of last week's issue), where different contractors agreed with the building owner to do separate parts of the construction, and in that case the court held that each contractor was an undertaker. In the present case one contractor agreed with the building owner to do the whole of the work, and he sub-contracted with the appellant for the painting work. The appellant was therefore not liable. Secondly, painting was not "construction." In *Wood v. Walsh and Sons* (1899, 1 Q. B. 1009) it was held that painting the outside of an old house was not "repair." There was no distinction between that case and the present. The decision of the County Court judge was therefore wrong. Mr. Temple Franks, for the respondent, contended that there was nothing in the Act to show that a sub-contractor could not be an "undertaker." In *Mason v. A. R. Dean, Limited*, it was decided that there could be several undertakers in respect of the construction of one building. If that were so, a sub-contractor could be an undertaker, and whether he was so or not was a question of fact in each case. The County Court judge found that in this case the appellant was an undertaker, and no appeal lay from his finding. Section 4 was not against the respondent. That section merely provided a remedy against the contractor in addition to that against the sub-contractor. If the sub-contractor was a man of straw, then the applicant could proceed against the contractor. That was the object of section 4.—The Court allowed the appeal.—Lord Justice A. L. Smith said that in his opinion the County Court judge was wrong. Though the judge's notes were very meagre, he understood the facts to be these:—Gould was a builder and contractor, and he contracted with the building owner to construct the building. Gould then entered into a sub-contract with the appellant, who was a painter, by which the appellant contracted with Gould to do the whole of the painting of the building. The appellant employed a man named Cass as a painter upon the painting work of the building. The building was a new one, and had never been painted before, and one point taken

was that the painting was "construction" within the meaning of section 7. That point it was not necessary to determine, because the other point taken was sufficient to decide the case. It was said that the appellant was not an "undertaker" within the Act; that Gould was the undertaker, and that if anyone was liable Gould was liable. The question, in other words, was whether a sub-contractor was an "undertaker" within the Act. It was said, on the other hand, that the respondent had the option of suing either the contractor or the sub-contractor, as they were both "undertakers." To his Lordship's mind this latter contention was not correct. That was not the meaning of the Act. "Undertakers" were defined in section 7, sub-section 2, so far as material, as meaning persons undertaking the construction, repair, or demolition of a building. In the present case, who had undertaken the construction of this building? The answer must be, Gould. In *Mason v. A. R. Dean, Limited*, a firm named Messrs. Moore and Sons had contracted with the building owner for the construction of a theatre, but under powers reserved in Messrs. Moore and Sons' contract the building owner entered into a contract with A. R. Dean Limited for the latter to do the decorative work. The deceased man was in the employment of the latter firm, and he was killed while at work on the theatre. This court held that, as A. R. Dean Limited had entered into a contract direct with the building owner to construct part of the building, they were "undertakers" within the Act, and liable as such. That was an entirely different case from the present where a contractor had agreed with the building owner to construct the whole building, and had let out part by a sub-contract to a sub-contractor. Section 4 was strong to show that a sub-contractor was not an "undertaker" within the Act.—Lord Justice Collins and Lord Justice Romer agreed.

HERALDRY.—V.

By GUY CADOGAN ROTHERY.

(Concluded from page 37, No. CCLXIII.)

Common Charges.

THE common charges used in heraldry are innumerable, and it is impossible to do more than give a brief résumé of the most important or curious objects employed.

As stated, the human body is borne either

HORN, STAINED.

DOUBLE-HEADED
EAGLE DISPLAYED.

ST. CATHERINE'S
WHEEL.

LEOPARD'S HEAD,
JESSANT-DE-LIS.

nude, clothed, or in armour; a *chevalier* is a knight armed at all points. But besides emblazoning the human frame in its entirety, limbs and other portions of the body are often borne as charges. An arm is borne *vambraced*

in armour, *manched*, clothed; or naked and *embowed*, or bent; the hand also appears either *enpommée*, open with the palm showing; or as a closed fist. A heart is a very common charge; it is often *distilling* drops of blood. Heads of savages, Saracens, and negroes are charges of frequent occurrence. Limbs are either borne *couped*, cut off with a smooth edge, or *eradicated*, or torn off, the leg being cut off at the hip or knee, and the arm from the shoulder or elbow. There are also *skulls*, *shinbones*, and *thighbones*. Priests, angels, and cherubs are sometimes borne, and one most singular charge called a *Prestor John* represents a bishop in full canonicals, seated on a throne, holding a naked sword between his teeth. A *virgin* is a young girl, for a *girl* in heraldry is a young stag.

The wardrobe has also contributed its share of heraldic emblems. We have shirts of mail, surcoats, hats and helmets, *murrions* (small steel caps), sleeves, technically called *manches*, and even shoes and hose.

Weapons of war are frequently used—the sword, axes, cross-bows, arrows, lances, and hand grenades; the sword is said to be *hilted* of such a tincture when the hilt differs from the blade. There are also *broad arrow head* and the *phœon*, *calthrop*: a four spiked implement so arranged that when thrown on the ground one spike always stood upright to keep off cavalry.

Hunting has furnished us with the *fetlock*, an implement placed on the leg of a horse in order to fasten it in a padlock; *barnacles*, or withers, instruments used by farriers to curb horses; and the hunting horn, which is frequently ornamented with a rim round the top and mouthpiece of a different tincture to the horn and is then said to be *enguché*. *Bird-bolts* are blind arrows, used to bring down birds without injuring their plumage.

Sometimes traders and craftsmen, or their children, were ennobled or raised to knightly rank, and these not infrequently ornamented their escutcheons with the implements of their late occupations. And thus we have *mallets*, *hammers*, *nails*, *spades*, and the *millrind*.

The celestial charges are the sun; the moon, in full or as a crescent; the stars; and the thunderbolt, which is represented as a straight bar, placed over two arrows in saltire, with wings and flames issuing from both ends. The quarter moon with its horns turned upwards is called a *crescent*, but with the horns turned to the dexter side it is said to be *in-crescent*, and with the horns turned to sinister side *de-crescent*.

Of vegetable charges the most common are *fleur-de-lis*, roses, lilies, *garbs*, or sheaths of corn, *trefoils*, *quatrefoils*, and *cinquefoils*. Leaves may be borne *pendant* or *erect*. The *fleur-de-lis*, or heraldic lily, differs very much from the lily of natural history, and indeed many heralds maintain that it was intended to represent the iris and not the lily. The terms *fleury*, *flory*, or *flowery*, are used to indicate that certain charges are ornamented with *fleur-de-lis*; thus we have a cross *fleury*, a border *flory-counter flory*. It is a common charge in English and Scotch heraldry, for the English kings were in the habit of granting permission to officers who had been successful against the French to add *fleur-de-lis* on their escutcheons, as marks of honour.

Trees are borne either *eradicated*, *couped*, or *fructured*; the first term being applied to a tree pulled up by the roots, the second to a tree cut off smoothly just above the roots, and the last to a tree bearing fruit. A group of trees growing on a mound is called a *hurst*.

Wreaths of flowers are frequently placed round the heads and loins of nude figures; besides this there are crowns of oak leaves and acorns, of laurel leaves, and roses. A charge is said to be *englanté* when ornamented with oak leaves and acorns; a charge is often said to be *verdoy* of some foliage, which means to say ornamented with leaves. A branch or leaf torn from the trunk, and thus appearing with a ragged edge, is said to be *slipped*.

The *castle* is generally formed of two towers, broad at the base and tapering towards the top, and a part of the castle is shown between each tower; there are three arched doors, one

in each tower and one in the centre building, and four oval windows. The *triple castle* has three towers, the middle one being higher than the other two, all three being joined together by a narrow piece of castle wall; the whole

FETTERLOCKS.

HAWK'S LURE AND
BELL.

TREE COUPED.

TREE ERADICATED.

length of the castle should be embattled; each tower has one arched doorway and one oval window. The charge of one single tower is constantly borne, but this charge should not be emblazoned a *castle*, but a *tower*. Castles were originally only given to warriors who had captured a stronghold, or to those who had successfully resisted a siege. Many charges are blazoned in differently *crénelé*, *castellated*, or *embattled*, when their outline is shaped of embattlements.

The *portcullis* is an iron gate, the upright bars of which, generally five in number, are armed with barbed spikes; at the ends of the horizontal bars are rings from which hang chains.

Of musical instruments we have, besides the hunting-horn, clarions (sometimes styled *rests*), organ pipes, hautboys, harps, fiddles, flutes, Pan's pipes, and the military bugle.

Books are emblazoned both open and shut. Rolls, and charters, with seals, &c., are also constantly seen. There is a curious charge consisting of little oblong objects, frequently borne strewn all over the field, which some heralds say were intended to represent letters, and others say bricks; they are called *billets*.

An *annulet* is a ring.

Mullets, or rowels of spurs, have five spikes and are pierced in the centre. *Stars* do not have holes and are sometimes borne wavy; stars, generally, have six or more points.

Masoned is a term applied to describe the lines formed by the junction of the stones in a building.

A *mound* is an imperial globe generally borne with a cross; a *mount*, or hill, is generally placed in base.

There are several terms applied to an escutcheon according to the manner in which its surface is divided. *Lozengy* is employed when the shield is covered with lozenges, alternately of two different tinctures. *Mascally* when the field is divided by diagonal lines into lozenge-shaped compartments of alternate tinctures, each being voided of a different tincture. *Lozengy-mascally* is a shield composed of lozenges and mascles. A shield may be *gutté de larmes* or *gutté de sang*, that is, covered with drops of blue colour, representing tears, or drops of red, representing blood.

Every trade and profession has provided heraldry with its own set of symbols. We have arches, bridges, capitals, carpenters' and bricklayers' tools, mathematical instruments, and so on. The cross has been ornamented with several architectural features, such as the crosses corniced, capitalled, banister, millrind, and carpenter's rule.

An Architect's Experiences in the Development of Design.

By EDGAR WOOD, A.R.I.B.A.

AS there are in landscapes certain expressions and effects which can only be fully realised by turning round and looking back, so there are, in our experiences certain times and periods of our past which can only be fully realised in importance when seen through a vista of years; and so now I know better than I did how important and fateful are the times in which our early impressions are to be formed, how important to our future will be the surroundings of our first five architectural years, and how they may determine for our unconscious youth whether we are to be inventors, creators, or copyists. I know better now how responsible is the work of the office head, and how much depends on the kind of support and assistance to which the architectural sapling is bound. My experience, though not by any means a large one, has been sufficient to show me that anything like an architectural and artistic office atmosphere, if not a rare one, is certainly one of a small minority, which to me means that the great majority of those practicing architecture are more fully and better equipped for a commercial success than an architectural and artistic one. Into which of these atmospheres chance may drop the enthusiastic student, is most vital to his future realisation; he comes at one of the most impressionable periods of his life either to disappointment, which often converts or drives him into the office hack, or to continuous encouragement and endeavour, which allows what is in him full and free development. My earliest architectural years were passed in an atmosphere where beautiful creative power as applied to building, and life in design generally, were drowned in the solemnity of commerce, tracing paper, and the checking of quantities; and so it is with some as it was with me, that real architectural education only begins with the advent of responsibility after the years of pupilage have passed or been survived.

I think every architect must have at some time or other attempted serious conclusions upon the relationship of the place to the elevation. In common with most others it was always my desire, but never my accomplishment, to give to a work its possible beautiful side, and I was in my early years led into the common error of approaching any building as an opportunity of producing an exterior architectural success. My plans, if not made through elevations, were certainly influenced by a possible exterior effect more than I now think was justifiable. I worked too often from some or for some particular result, some interior, but more often some exterior, effect or treatment, and attempted to produce the same by arrangement of plan in a somewhat similar manner. This method, which I am led to believe is not by any means an uncommon one among the unexperienced, I have long since discarded as being totally wrong; it is putting the cart before the horse, and it brings about subsequent evils, not the least of which is mind stultification, which is difficult to eradicate. It is a process of working which has its original source in a too strong tendency to artistic superficialism, and is undoubtedly due to an unequally balanced judgment.

I have found it much more satisfactory to start from the plan entirely, making it thoroughly useful and fit to the extent of almost ignoring the elevation, so far as your mental vision will allow you to ignore it. After having thoroughly satisfied yourself of the arrangement of your rooms and requirements, then make your elevations, letting them grow, letting them suggest and almost make themselves in the first instance, which I find paves the way for modifications in the plans as the elevations may require for their improvement in balance and construction, always, of

course, being on the guard of endangering the utility of the plan. This is the total opposite of my early efforts; it means changing the concentration of thought from the elevation to the plan, from the æsthetic to the utilitarian, from the picturesque to the constructional, all of which not only considerably improve the working and useful portion, but also improve the æsthetic and architectural result, as nothing satisfies the balanced and cultured vision so well as the really useful dignified with proportion and refinement.

I know it is often stated that elevation and plan should be worked together, that they are in themselves inseparable. That in the completed design of the building they should appear inseparable I quite admit; one should account for the other from the bottom to the top; but in working the plan I question if it is possible, in buildings other than those devoted to merely monumental purposes, to carry in your mind more than a vague idea of the general tumble of your elevation. You may at the very first, and perhaps ought to, have decided that your building shall be either long and low, or narrow and tall, or even square. But much beyond that I think it almost becomes impossible to have in your vision, and I question if it would be advisable if it were possible, because you can even in buildings have such a thing as a too laboured result. Take a house. There are some men who work not only with the idea of producing a good working plan, but are not content until they have arranged and provided for every piece of furniture that has to go into the house, and they do not consider the drawings are complete until this is done. The desire of these architects to control the fittings, the furniture, the drapery, and all the furnishings of a house, both inside and out, is to me perfectly correct, and generally imperatively justifiable, subject to the condition that they have made themselves competent to do so. I rather question, however, the advisability of their method of procedure, of planning every detail of finishing before the completion of the drawings. In theory it sounds all right, but in practice my experience tells me it is very likely to destroy the beautiful results of accident in effect. You cannot realise or make the work suggest on paper quite in the same way that the building will do for you. In working your plan an eye need only be kept upon the place for the principle pieces of furniture for which the rooms are intended, such as the bed for the bedroom, the table and sideboard for the dining-room, and the books for the library; you are then left free to devise the particular details and arrangements at some subsequent and more opportune time. Enough evil for the day thereof I think applies. Try to remember the reflections deduced from the analysis of the picturesqueness of old buildings, and more especially of old towns. Some of the features that appeal so strongly to the artistic mind are these continuous surprises, resulting from beautiful accident, which one instinctively feels could never have been designed with such pleasurable results. They are the beauties and delights that belong to accident only, and one realises their charm perhaps stronger if we compare them with the studied results of carefully planned estates for suburban and residential property; how they suffer from the absence of that quality of accident. They are barely suggestive of humanity in their stiffness and regularity, they rather repel than invite, and make one long for an error in their setting out, or a blunder in their levels which has annihilated the original intentions beyond recall.

Then when we design, do we never question ourselves from what source should we start? From what stock should our ideals be formed? What are the seeds from which we wish to produce the fruit? My thoughts have often led me to wonder if the advice so widely and so often given to students to lose no opportunity of sketching and particularly measuring old work has not been given too literally and without caution and qualification. Measuring can be made indispensable if done with object and reason, but blindly performed can produce evil with little benefit. I feel its value when followed after appreciation or

admiration; it is then the only way to discover and realise the hidden and subtle beauties of work in existence. Sketching such parts, though of a certain value in itself, is doubly valuable in conjunction with measurement and scale, as it then becomes the practical and recorded analysis of cause and effect. But I have found that sketching, though it may stock your memory and increase your resources to a great extent, may by that very process of storage have crowded out and diminished another equally important faculty, that of invention. I have been surprised, almost overwhelmed, by the sight of buildings which to me were exceedingly beautiful, which I have afterwards discovered were the works of men who from old work, or even any work, have comparatively measured little and sketched little. From the human figure and from nature I find they have studied deeply, very deeply, and they, having strong artistic tendencies and strong natures, have started, so to say, from the bed-rock of construction, and by sheer inventiveness of their own produced works and results which to me have the charms and beauties of the old with the very greatly added quality of freedom and beautiful originality or personality. No academic composition seems to have cobwebbed their minds. They have not fallen back on the traditionally beautiful or produced a result out of old and beautiful features in a rather different form. This, to me, is absolutely the type of mind of the ideal, because it implies that they have been able, without leaning continuously upon the crutch of research and reference, to produce exceedingly satisfactory results. I do not by any means say there should be no reference and no research or training required but the kind and type I allude to. Too much imbibing of old work may make you a scholar, but it may be at the expense of invention. What we want is that that training and material ought to be absorbed which will enable one to come through a problem alone, and it is the men who have done this that we call original.

Mr. William Morris once said that when we sit down to design we have before us, and we cannot help it, some example in our mind, however visionary, of something, some composition which we have seen and admired before, and which is our ideal for the moment of the work we have in hand. I believe it is so, and I suppose it is only the very strong ones or the very bad ones amongst us that either have this vision in a very misty form or are able to obliterate it from their memory to make way for their own. I do not want to leave the impression that I think originality the only quality to be aimed at; rather let us have beautiful individuality tested by example of recognised beautiful result.

Originality for the sake of originality is artificial. It is one of the most vicious, affected, and conceited ideals that can clog the mind of the designer. Natural originality is the outcome of effort in search of higher ideals. Up to a certain period, if not to the end, all must be influenced by the work of others. It is bound to be so, and cannot be otherwise, and it is right that it should be so. Nothing comes out of nothing. One man can add but very little to what has already been done, and it is the natural and unconscious selection that we may make as to what shall influence us that largely determines the level of work which we do. The reason of the bulk of bad work in design and everything else is that so many minds are incapable of being influenced by the presence and existence of work of the very highest type. They may be prevented by want of intelligence, by commercial considerations, by timidity—but whatever the cause it is some force which is stronger than the power of their appreciation can surmount and overthrow. And one of the very characteristics of the artist is that you have the man who sacrifices everything and everybody, himself included, to the perfection of his work, to the passion for efficiency, which is the true master-passion of the artist.

I have already alluded to some men having trained themselves in design largely from the influence of drawing the human figure, and from the drawing and deep study of

* A paper read before the Birmingham Architectural Association on February 23rd, 1900.

natural life. The work of these men has been of that type which has, perhaps, made the greatest impression upon me. I have found it the work which, perhaps, I have admired the most; it possesses a character of directness, of subtlety or refined life and vigour, which I have felt to be most refreshing. But perhaps the most impressive side which their work has is that of range and completeness. To the ordinary mediocre mind, the wide scope of their efforts appears almost incredible. They have not been content, like many of us, to consider their labours complete when the building is swept out, but all the carving has been designed and modelled by their own hands, the leaded lights, the decoration, and even to the figured fresco has not only been suggested but even painted by them, and painted well. Personally I have drawn comparatively little from the nude, but from flowers and tree growth I have made, and still make, a fairly large number of studies, and my experience is that they count amongst the most valuable results, both directly and indirectly, that I have ever spent time upon. Ruskin in his "Two Paths" writes: "Architects who have no knowledge of sculpture, or any other mode of expressing natural beauty, endeavour to substitute mathematical proportions for the knowledge of life they do not possess and the representation of life of which they are incapable. How this substitution of obedience to mathematical law for sympathy with observed life is the first characteristic of the hopeless work of all ages—for which no future was possible but extinction."

Although anything approaching to definite rules is, as Ruskin says, "fatal to all good art," there are, I feel assured, certain qualities (and some of them by no means abstract ones) which no good architecture can be without, and it is the analytical discovery of these rather elementary qualities which, unfortunately, sometimes come rather late, and which have certainly almost accounted to periods in experience. It is the presence of these shortcomings that causes the disagreeable side to almost all of our past efforts. That these regrets are all to be entirely avoided, of course is impossible; they are the barometer of our improvement, registering the progress of visionary education, and it is in these particulars that the collective capacity of architects can be so valuable to one another in the detailing of their honest and open experiences and criticism. As I look back and see what a great change some of the most simple discoveries make in effect, I cannot but be surprised that so elementary an item was not more easily and earlier effected. For instance, the attention to harmonious texture and quality of surface in materials. I suppose it is not a very deep discovery or study, but what a surprisingly large number of our modern buildings are anything but satisfactory on account of the neglect of this particular. It shows itself to me in many ways in the almost blind worship and continuous use of large masses of Ruabon and similar types of facing bricks in preference to the beautiful walling results to be obtained with common bricks. Then the fatal effect of combining in close proximity polished marble and polished granite with the dull materials of stone and brick. The too often lavish use of polished ashlar stone in preference to the more simple and more refined of what are known as common outsides in walling. The very common, coarse, and vulgar result known as parpoint finish in masonry, intensified in vulgarity by its combination with finished stone dressings. The fatal mixing of glazed and coloured bricks in interior corridors, &c., will dull plaster and sometimes stone. The combination of tiles having highly-glazed surfaces with a framing of wood and metal in fireplaces, &c. The incongruous companionship of highly-polished or heavily-varnished woodwork with the comparative refined and dull surface of wall paper or drapery, and, generally, the overwhelming use of varnish and of glittering surfaces everywhere. The avoidance of polished and reflecting surfaces in mass, I feel convinced, is quite the right aim. In nature you seldom find it otherwise; the sparkling and reflecting portions with her are always in small quantities or in

passing effects; the normal condition of landscape, of flowers, of flesh, is one in which the surfaces are almost entirely dull and dry. Reflecting surfaces invariably destroy all repose and rest by their violent contrasts, and they destroy the solidity of materials, giving everything the effect of surface treatment only; whilst, if sparingly used, or, perhaps better still, allowed by themselves to develop by normal and natural usage or wear, they will add to all interiors that little glitter of which so little is required. That the public should do these things in buildings where they think no control or advice is better than their own is perhaps not very surprising; but when architects are so greatly guilty, why have doctors at all?

Another qualification to which a name can be given, and one which I have realised is so essential to interesting design, is that of accent. To a great extent it goes hand in hand with the quality of interest. I find it very difficult to say anything about it, as it is so very largely a question of sight; but accent in design is the opposite of what I understand by the term "all-overish." When not recognised by a name I think we all try to produce it, but perhaps do not always succeed, or perhaps produce the accent in the wrong place as some people do with their h's. At one time I had an almost infallible opinion that accent or richness should for some reason or other be somewhere at the top of the composition, wherever that might be. I now have somewhat different views and, in consequence, cannot say where I think it should be represented, except that it should be somewhere. I also had the opinion that all accent could have no other legitimate expression in any form other than ornament of some type or other. I have now also somewhat expanded and feel I cannot express an opinion as to what form it should have as long as it is beautifully and comfortably expressed, all of which means that while one can be fully alive to its value one is content to take advantage of what may suggest itself, or even reason out the same from the natural growth of the design and plan. It may be a gable or a group of gables, a projection of plan, a central feature, a tower, a door, or a bay; it may be a piece of ornament or a statue; but it must be something.

You enrich and emphasise what you individually feel should be important and to which the eye should naturally travel and be focussed, and it is the selection of what should have the accent on your composition, upon what the concentration should be, that shows the respective power and skill of the architect. I often think that it is in this direction that the difference between the architect who is an artist and the architect who is not somewhat strongly asserts itself. The inartistic man invariably squanders his features and his ornaments equally over the whole; he is lavish without selection, which produces an equality that denies distinction; and the resulting monotony, though often costly, fails to arrest permanent attention.

Time prevents me alluding to many other directions, but, generally speaking, design development in my experience has meant coming from the ornate to the simple, from the use of ornament to almost the avoidance of it, as being not only in itself largely unjustified, for one must never forget that ornament has no justification for its existence except that it be beautiful, and therefore it must be always difficult to produce it. I cannot now look upon it as of such little importance that it can be frivolously or carelessly employed, but rather that it demands the serious attention and strain of the designer as the jewels of the composition. Much of my time of later years has been taken up with an attempt to gain some knowledge and some even superficial familiarity with colour. As one's idea of completeness expand as years go by (which is almost inevitable) we find ourselves unsatisfied until we have equally controlled the work to its last touch, and it is the last stages which, though so often the superficial ones, are also those which cover the greatest area; therefore becoming of such importance that they cannot be ignored or left to the independent treatment of others.

We have all had the depressing experience of seeing our work, if not retarded, certainly not assisted by the result of the co-operative efforts of decorator and client, a proceeding which alone makes me realise the absolute necessity of controlling by the same mind the aesthetic to the end; for how wide and important to an interior is the very superficial treatment of the plaster walls, the colour and treatment of the woodwork, the carpets and the hangings; the great difference it makes in the way you use that colour and even in the way the painter technically puts it on; how an interior can be made pleasurable and comfortable when only two colours (or even one if it be good) are used, and how the same can be hideous with a legion of bad colours.

Finally, I wish to mention another quality which I feel to be imperatively important—that of variety or interest. I think we could safely say that, if this quality were never absent in the whole of our architectural results, we should have arrived nearer perfection than ever has been reached before. To give that judicious quantity of variety or interest to all we do reads pretty well the same as "Act is long and life is short."

The full value of subtle variety can, I think, only be even partially realised by the earnest student of nature. It is here that he recognises the power and beauty of it to the full, the entire absence of anything approaching monotony, not only in what the naked eye tells him, but even with the help of the most powerful magnifiers, how the interest and variety in all her parts never fail. Yet with this lesson continuously before us the great majority of our architectural works are strongly characterised by monotony. Our modern towns, our modern streets are made disagreeable by monotony. The materials we use the most and the reason of their being used is because they are monotonous, and those materials which have in bulk beautiful variety and interest are so carefully sorted and arranged that when used they shall be monotonous. Manufacture and material are scientifically studied that all properties and processes making for broken colour and texture shall be eradicated or controlled in order to produce monotony.

It is often deemed almost the ideal of "correct taste," whatever that may be, always to design our building by halves; one proportion, one type of window, of chimney, of door, are often thought sufficient for a whole floor, or even a frontal façade. These materials, and the world is full of them, which are beautiful and lovely by their variety and interest, lovely beyond the capacity of man to excel, are vanished for inferior work and degrading service. Hence it is why so often the buildings of no importance—those too poor to pay, those which have not been honoured by the architect—have no disagreeable side. That is the reason why so often the backs of our houses which have been considered worthy of but little attention, and have escaped our academic corrections of style and professionalism, have been allowed largely to do their own and become comparatively interesting. It is also the reason that the picture painter in search for material and subject so seldom is found where the modern architect has been; he may precede, but he seldom follows us.

To our clients we apologise for every stain in stone and every twisted brick, and often our entire efforts are concentrated to produce a whole which nature contradicts with the full force of her example and teaching. We deny our buildings the one quality without which our architecture can never be beautiful, and we expend no end of time and money in producing the hideous artificial when the lovely and natural is lying at our feet. If we will persist in banishing all materials which yield a surface interesting in colour, and will persist in giving to materials a surface and treatment which are foreign to their nature, our buildings, however rich they may be in every other respect, however skilful in the arrangement of masses, however cleverly accented, however beautifully grouped, however refinedly detailed, must be in the full aesthetic sense, in the full enjoyment of what

beautiful building can yield, only a partial success. If we would only use those materials which have been made beautiful by their natural formation and growth, and use them well, there would be even less necessity than ever for the acres of features with which we crowd and distort our designs, architecturally untreated walls would lose their terrors, plain surfaces would take their place and prove their value as against enriched ones; and proportion and mass would gain the attention and value they so richly deserve and repay.

From what I have said it may have occurred to some that this is all right so far as it goes, but it does not represent that phase of architecture which is the beau ideal of so many and is termed the "monumental." It may be in the direction of the picturesque and perhaps the romantic, but it leaves almost untouched the styles, the orders, and the whole paraphernalia of architecture with which we are accustomed to clothe our work, and so gain it that distinction which we consider exalts it above mere building. If such thoughts and conclusions should have arisen I should acknowledge that in one sense they would be correct. Any attempt at clothing with super-added features has never had any great attraction for me, and I cannot consider that the use of them, even however great their scale, is the only interpretation of the quality of "monumental." I may be mistaken, but I have the impression that the word monumental with a great many means the use of the orders, the pilasters, shafts, cornices, columns, and the host of features which one sees so lavishly employed in our architectural exteriors. If this is so I can only say again it is an interpretation of the word which attracts me but comparatively very little.

To me that which is monumental is that which is a monument, in the very broadest and highest sense of the word. In nature to me it is represented by the sensations produced in the contemplation of mountains, of cliffs, of clouds, not necessarily of great size, but always features of distinction, works of grandeur and exalted nobility. And I have never felt that the characteristic of these, as we see them in bulk, that the chief power of their attraction is one of superadded or surface treatment; it is more often their sublime simplicity, their strong lines of bone, of formation and construction, which I feel so impressive; their suggested element of reserve power and hidden force in contrast with their surroundings and environments; it is the echo of these qualities when they appear in architecture or building which makes one feel that the work is monumental. I admit, if it is an admission, that the buildings both ancient and modern which appeal to me the strongest, which revive or produce enthusiasm, which enforce effort, and which make me realise the greatness and the justification of architecture, are those where orders, &c., of whatever period, whether of classic or Gothic influence, have no place; or, if they be present, it is in such a way, in such form, and such quantities as to only count or impress as trifles in the whole. Those buildings to me are monumental which, though ingenious, are never clever. They are beyond the reach of the merely clever. They are beyond the reach because they are great and big by their echo of human reserve and simplicity, great and big by reason that, however frequently and continuously contemplated, their noble influence never diminishes, and their power of appeal to our highest emotions is never exhausted.

The C. and S.L. Electric Railway Extension to Moorgate.—The Moorgate Street station and general offices of the company have been built by Messrs. Mowlem and Co., under the superintendence of Mr. T. Phillips Figgis, A.R.I.B.A., of 28, Martin's Lane, Cannon Street. The building is of brick with stone dressings. On the ground floor is the booking hall, just beyond which are the two immense double lifts, each of which will take over fifty people. The company's offices are on two floors, and the remaining floors are to be let as offices.

OUR SHILLING FUND.

PROGRESS OF THE SCHEME.

THE chief feature of our Shilling Fund during the past few days has been the number of applications we have received for our collecting forms. This is gratifying (as far as it goes), the special object of our fund being to gather in the small subscriptions which would otherwise be lost. We have plenty more forms which we shall be pleased to send to anyone who will make good use of them. We would point out, however, to architects and others who have not yet subscribed that though ours is "a shilling fund," we are not less willing to accept guineas. Our offer to send a copy of "Specification" as a slight acknowledgment of their efforts in the good cause to every collector or contributor of twenty shillings or more still remains good. We shall publish a further list of subscriptions next week.

With regard to the progress of the general scheme for the erection of the proposed Homes of Rest for discharged soldiers, we are informed that by the end of February the value of the gifts of materials promised amounted to over £12,500, and that nearly £1,000 in cash contributions had been received. The value of the buildings and works as proposed by the scheme may be taken at nearly £25,000, including the drainage system, furnishing and electrical equipment. There is thus still another £12,000 to make up. The material principally required is timber; as yet scarcely any timber has been given, the timber trade being the only one of the building trades that has not come up to the scratch. Further supplies of lime and cement, red facing bricks and joinery, are also required. As regards cash, about £6,000 is still required.

It is hardly necessary to point out the urgency of this matter; the number of the wounded is constantly increasing, and it is surely desirable that the Homes which are to form the Building Trades' Gift should be prepared for their reception with the least possible delay.

The following additional gifts have been received by the executive of the gift:—

Messrs. Graeves, Bull, and Lakin.—Selenitic lime for six homes and service block.
Messrs. Matthew T. Shaw and Co. Limited.—Light iron joists for concrete floors.
The Albion Clay Co.—The intercepting traps and necessary stoneware gullies with iron gratings.
Messrs. William Oliver and Sons.—The wood for 2,500 ft. super of cupboard fronting.
Messrs. John Grover and Sons.—Forty doors.
The Fireproof Partition Syndicate Limited.—200 yds. "Cunah-Wright" Partition.
Messrs. Jacobs, Brothers, and Co.—50 tons Portland cement.
Messrs. Hawkins and Son.—One truck load grey stone lime.
Messrs. Thomas Turner and Son (Lightcliffe, near Halifax).—Steps for one of the Homes.
Messrs. Peace and Norquoy (Manchester).—One Patent Folding Partition.
Mr. W. S. Norman.—Six Outside Green Blinds.
Messrs. Kemp, Collier and Co.—Scaffolding Poles and Putlogs for two Homes.
Messrs. Shanks and Co. (Barrhead, near Glasgow), per Mayor of Windsor (second gift).—One Bath.
Messrs. Crogan and Co.—Three 450-gallon Cisterns.
The London Drawing and Tracing Offices.—Sun Prints and Photo-copies of the Working Drawings.
The International Electric Co., Ltd.—Electric Light Fittings.
Messrs. Johnson and Phillips Electric Cable Works, Ltd.—Three coils of 600 megohms vulcanised and braided cable.
The Worthington Pumping Engine Co.—Feed-water pumps required.

Correspondence.

The Architectural Museum, Westminster.

To the Editor of THE BUILDERS' JOURNAL.

PALL MALL, S.W.

SIR,—The state of the Architectural Museum in Tufton Street, Westminster, is one that requires some attention. When John Ruskin joined the Council in 1877 he presented to the museum an extensive collection of casts from France and Venice, the classification of which takes up two or three pages of the catalogue. To-day the whole of the room devoted to these casts is partitioned off from the rest of the museum, and marked "private." Inside it is almost hopeless to make anything of the existing fragments. They are unlabelled, unclassified, with the numbers mostly gone or undecipherable. Such things as the capitals from the Ducal Palace, which Ruskin wanted to be within the reach of all, are not to be found.

It is the same with the rest of the museum. The casts from the English Cathedrals, which might be so valuable a series and such an aid to the study of Gothic architecture, are in hopeless confusion, especially in connection with the tattered copy of the catalogue in the hall, dated 1877; even of this no copies can be obtained, and an attendant once told me that a number of copies might have been sold were they to be had. The Architectural Museum should be to Gothic what the British Museum is to classic architecture. At present the building seems to be handed over to an art school, and the study of its contents, even if they were in a less confused condition, is almost out of the question. One meets with "private" at every few steps, and many of the casts must be inaccessible to visitors. Much as we may desire to see a memorial to Ruskin in Westminster Abbey or the National Gallery, it would be more to the point to try and rescue some of his work. It seems sad to think that his labours should be wasted and destroyed when they might be of so great an aid to the study of Gothic architecture.—Yours faithfully,
MAX JUDGE.

The Sanitary Institute.

To the Editor of THE BUILDERS' JOURNAL.

PARKES MUSEUM, MARGARET STREET, W.

SIR,—Now that it is becoming the general practice of local authorities to require some certificate of competency from newly appointed sanitary officers, the Council desire again to direct your attention to the examinations for inspectors of nuisances under the Public Health Act, 1875, which have been conducted by the Sanitary Institute for the past twenty-two years. The certificates granted by the Institute are accepted by over two hundred local authorities, including most of the principal towns of England, and the certificate is one of the most reliable testimonials that a candidate can produce for this appointment. Since the public work of the Institute was commenced in 1876, it has examined 5,400 candidates, and the Council are glad to note the general improvement in the status and capability of these officers throughout the country, which has followed its efforts. Examinations have also been recently established by the Institute for inspectors of meat and other foods, so as to give practical effect to the order issued by the Local Government Board upon the report of the Royal Commission on tuberculosis.—Yours faithfully,
E. WHITE WALLIS, Secretary.

[A pamphlet relating to their examinations (which, for the convenience of candidates, are held at various centres) is issued by the Sanitary Institute at 6d. net.—Ed.]

Bricks and Mortar.

APHORISM FOR THE WEEK.

"Architecture is frozen music."—MADAME DE STAËL.

Our Inset Plates. On page 70 of the present issue particulars will be found of the tenements on the Boundary Street Area, Bethnal Green, N.E. The plans for these buildings were prepared by the London County Council. The Romford Public Baths are now being erected for the urban district council. The accommodation comprises a swimming bath, six private slipper baths, with waiting and committee rooms and establishment laundry. On the first floor are rooms intended to be used for technical instruction, and on the second floor are the rooms of the superintendent. The swimming bath will be provided with a movable floor, so that it can be used as an entertainment hall. Space is provided in the basement for storing as well as for the necessary boiler house. The front portion of the building is faced with red bricks and Bath stone dressings, and the rear portion is faced with stock bricks. The building is being erected from the designs and under the superintendence of Messrs. Harrington and Ley, of 108, Fenchurch Street, E.C., by Messrs. Thomas Bruty, builders, of Hornchurch, Essex. The accommodation of the house at Sampford Peverell, Tiverton, comprises a large hall, dining room, drawing room, study, kitchen and offices on the ground floor, with six bedrooms and bathroom, &c., on the first floor. The materials proposed to be used are local stone for the ground storey, with half-timbering and green slates above. The large overhanging cornice is of wood, and the bay windows near the angles of the building, which have deep ornamental lead aprons between the ground- and first-floor windows, will also be constructed of wood. The design is by Mr. Cyril E. Power.

The Alexandra Palace.

A SPECIAL emergency meeting of the Hornsey District Council was held last Wednesday to discuss the proposed purchase of the Alexandra Palace and Park as a permanent open space. Seven years ago an attempt was made by Mr. Littler and Mr. H. R. Williams to effect a purchase for something like £260,000, but at that time the County Council had no power to contribute. The present scheme is more modest, though it includes all the essential features of the larger undertaking. It includes the building, which cost £350,000 to erect, and consists of a large central hall capable of seating about 20,000 persons; a magnificent organ put up at an expense of £20,000; a completely fitted theatre, concert room, picture galleries, courts, covered winter gardens, and range of dining rooms and kitchens, covering in all eighteen acres of ground, with an under-floor having entrances from the sloping terraces. The area of the land is 134 acres of freehold (which can never be built upon), and twenty-eight acres of long leasehold at a moderate ground rent. It is also proposed to purchase The Grove, consisting of ten acres of splendid woodland, situated on the west side of the Palace, for which £11,000 is asked. The Grove is interesting as a favourite resort of Dr. Johnson. It may be noted that twenty acres of land in the immediate vicinity of the Palace recently realised from £1,500 to £2,000 per acre. The Alexandra Palace has had an unfortunate career. The original building was part of the Exhibition of 1862, and was moved to Muswell Hill. It was opened on the Queen's Birthday in 1873, and was burned down on the 9th of the following month, the ruins remaining an object of public interest for some time. Ultimately the Palace was rebuilt, and was opened under the management of Mr. (now Sir) Edward Lee, who was knighted for his efforts in connection with the Dublin Exhibition. For a while the undertaking was a great success, one Bank Holiday seeing the record attendance of 105,000 people. In 1876 the Palace went into liquidation, and it reverted to the

London Financial Association, who then leased it to Mr. Jones, formerly associated with the Crystal Palace. Afterwards Mr. Willing took over the responsibility. For the last two years the lessee has been Mr. T. J. Hawkins, but again the speculation was a disastrous one, and the property was taken over by the London and Middlesex Freehold Land Company, Limited. At the meeting referred to above it was resolved to raise £120,000 as a Middlesex county fund, so that there is every prospect of the scheme being brought to a successful conclusion.

A New Westminster Building.

On the east side of the Roman Catholic Westminster Cathedral is the new "Archbishop's House," which is to be ready for occupation next July. It is built of red brick and stone, materials similar to those used in the construction of the Cathedral. The right wing will form the library. There is on the ground floor a large entrance hall, dining room, committee rooms, and secretarial offices, with a corridor of 105ft. in length; on the first floor are three reception rooms, leading one into the other, of a total length of 101ft., with a width of 35ft. The Cardinal's private suite of rooms and chapel are also on this floor. Adjoining the house, and connected with it, is the Diocesan Hall, 104ft. by 35ft. The Cathedral, the Hall, and the house will form one continuous block of imposing buildings of about 550ft., and occupying the whole length of Ambrosden Avenue. At the back of the hall and house, space has been reserved for the Cathedral Clergy House and a Benedictine Monastery.

Separation of Design and Craftsmanship.

IN his address to the students of the Royal Female School of Art, on the occasion of the distribution of prizes, Mr. Hugh Stannus commented on the manner in which of late years design and craftsmanship have been separated. He has certainly hit upon a curious anomaly in our system of art education, upon a working paradox in accordance with which teachers who have no experience of handicrafts train students to make designs that must be carried out by workmen who have no knowledge of art. The results of this disjointed arrangement have certainly not been happy. A tentative and unpractical type of design has been created; something that is more showy than useful; and the real object of decorative work has been forgotten. It would certainly be better if students could be taught to put their ideas into permanent shape instead of being obliged by the insufficiency of their technical education always to depend upon a mechanical executant. It is in this respect that the present movement towards a revival of the arts and crafts has special interest, as no man can expect to execute another man's design with the spirit of the designer himself—that is not transferable.

Ancient Monuments Protection.

A BILL has been introduced into the House of Commons by Lord Balcarras, M.P., and supported by Sir John Brunner, Mr. Carson, Mr. Jebb, Sir John Stirling Maxwell, and Mr. Bryce, to amend the Ancient Monuments Protection Acts by extending the provisions of the Ancient Monuments Protection (Ireland) Act, 1892, to this country. The Bill proposes to give power to county councils to purchase and preserve any monument situated in any administrative county or in any adjacent county, or to undertake or contribute towards the cost of preserving, maintaining, or managing any such monument. It is also proposed to empower the Commissioners of works and county councils to receive voluntary contributions towards the cost of maintenance and preservation of any monument of which they may become the guardians or purchasers. Any monument placed in charge of the commissioners or of a county council is proposed to be exempted from rates, taxes, and duties, including what are known as death duties. There is very little chance of this measure becoming law unless it is supported by the Government, or of its effecting much good

even if it should become law, considering the indifference of local authorities with regard to works of art. The title of the Bill is misleading, the word monuments in this country being understood to apply to sepulchral monuments only and not to buildings, as in France; but this is probably necessitated by the circumstance that the Bill is an amending Act, and it is incumbent to repeat the title of the principal Act.

Paris' Leviathan.

FRANCE has now her temple of waste paper. The huge building at the corner of the Rue Cambon and Rue Mont-Thabor has been completed and will be filled with the records of the Cour des Comptes. Each of the twelve storeys, two which are in the basement, has fourteen windows facing on the Rue Cambon and eleven on the Rue Mont-Thabor, and each comprises seventy-two rooms, making a total of 864. There is space for storing 60,000 *dossiers* in 60,000 compartments; every compartment is of cement, so that only one *dossier* may burn at a time, if needed. This is perhaps a pity.

The English Cottage of To-day.

IN the late Charles Kingsley's book "Yeast," the existing degradation of the English agricultural labourer is the theme. Mr. Archibald Marshall, in this month's issue of "Macmillan's Magazine," laments "The Destruction of English Villages." He says: "When a new church or new buildings are erected we all have something to say as to whether the architect has been successful or not, and houses for the occupation of the wealthier classes are being built all over England with taste and understanding. What about the cottages? For every church and school or big house there must be a hundred cottages built in the country every year, and it is no exaggeration to say that ninety-nine of them, so far from adding to the beauty of an English village, do something towards destroying the beauty that already exists. Go through any half-dozen villages in England, and see whether I am not right. The only exceptions are when a landowner has the taste and the will to save or to add to the beauty of his property, for the occasions on which the local speculative builder, who is responsible for the great majority of these modern eyesores, has the taste and the will to do something better are so few that they may be left out of account. It cannot be too much insisted on that wherever a new cottage or group of cottages is built in the country to-day, it is as a rule so hideous, so out of sympathy with all its surroundings, as definitely to destroy the charm of the spot where it is built, from whatever point of view it may be seen. And these brick boxes with slate lids, as they have been well called, are being built all over the country day after day, year after year. Is it not a monstrous thing that the beauty of rural England should be destroyed in this way, destroyed so quickly and so unfailingly, while we are boasting that the ugly, tasteless architecture of the immediate past is becoming more and more rare in buildings of greater pretensions? The remedy the author suggests, is the formation of a society to supply the small country builder with working drawings for his erections."

A City Improvement.

Thirteen years ago it was decided that the Cheapside end of Newgate Street should be widened. The work has now begun. The block of houses between Panyer Alley and Paternoster Row is being demolished so that the line of frontage at this point may be set back. It will not be a heroic remedy for the congestion of traffic at the junction of Cheapside, Newgate Street, St. Martin's-le Grand, and St. Paul's Churchyard, but it will afford some measure of relief for the 100,000 vehicles and the 30,000 pedestrians passing here daily. The cost of the improvement will be close upon £156,000, half being borne by the City Corporation and half by the London County Council. As a result, Newgate Street at this spot will be widened from 44ft. to 70ft. and the junction of Cheapside with St. Paul's Churchyard from 45ft. to 65ft.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Initials L.S.A.M.

CARMARTHEN.—W. V. M. writes: "What is the meaning of the initials L.S.A.M.? I find them after the name of an architect who advertises in the local papers."

The initials are unknown to us and have no recognised significance.

Book on Fitting-up Offices.

HORNSEY, N.—J. J. C. writes: "Are there any works published that deal with the arrangement and fitting-up of offices for clerical staffs of large manufactories?"

There are no books of this description in existence.

A Book on Drawing Columns.

LIVERPOOL.—D. W. writes: "What book can I get giving all dimensions for drawing out columns?"

The best small book for the drawing of columns is, "The Student's Instructor in Drawing and Working the Five Orders of Architecture," by Peter Nicholson (dated 1839, post free for 4s. from B. T. Batsford, 94, High Holborn, W.C.).

Book on Book-keeping for Builders and Contractors.

GLASTONBURY.—AVALON writes: "I should feel obliged if you could give me particulars of any good book on book-keeping for builders and contractors."

The best book is "Builders' Book-keeping: a Perfected System." By Sidney Saker. Price 3s. 6d. net. Mr. Batsford, of 94, High Holborn, W.C., will supply it.

Merits of Iron and Wooden Bungalows.

LONDON, W.—R. A. J. writes: "What are the relative advantages and disadvantages of iron and wooden bungalows? Which is the better? Is an iron building on an eminence specially likely to be struck by lightning?"

An iron bungalow would most certainly be ugly, and would be hot in summer and cold in winter, while one built of wood could be made exceedingly picturesque and would be cool in summer and warm in winter. Either, if built on an eminence, would be liable to be struck by lightning, but would be perfectly safe if properly protected by a lightning conductor connected to all external metal work and carried down to damp earth. G. A. T. M.

Drawings Required from Probationers R.I.B.A.

TAUNTON.—P.R.I.B.A. writes: "The R.I.B.A. kalendar says as follows: (a) Sheet 7. One sheet containing diagram of timber-framed roof truss not less than 30ft. span, with the nature of the strain on the several parts marked thereon, &c. What is meant by the nature of strain on several parts marked thereon, and how would they be shown? (b) Sheet 9. A sheet of details of joiner's work in doors, windows, and fittings shown in plan, elevation, and section, &c. Does this mean a sheet of details of a door or of a window; or does it mean a sheet of details of both doors and windows? (c) May the sheets of drawings be elaborately coloured as is sometimes done in offices, or are the drawings to be left in black and white?"

(a) The stresses would be either "tension" or "compression," which words should be written upon the members subject to these stresses. The word "strains" is here improperly used. (b) Use your own judgment. Measure good, sound work in preference to

copying, and fill your sheet. If you have room for both door and window, insert both. (c) Finish as working drawings, using a thick line and strong distinctive colouring to differentiate unmistakably between the various materials used, and figure all dimensions. G. A. T. M.

Girder to Support Gallery.

LEVENSHULME.—CLIMAX writes: "Would a church gallery of about 39ft. span by about 16ft. deep be safe without pillars, provided there were two iron girders across the span? If so, what size of girders would be required? If not, could the pillars be under the second girder, as they would be most awkward in front; and should the front girder be cantilevered from the second?"

The gallery could be carried by one girder supported on the wall at each end, and two rolled joists 12 x 6. The load on this girder would be about 32 tons, allowing 2 cwt. per ft. sup. as the load on gallery. The maximum stress in flanges would be $\frac{Wl}{8d}$ and, taking the depth at 3ft., this would equal 52 tons. Allowing 4 tons stress per square inch in compression, the top flange would require 13 sq. in. sectional area; say two plates each 15 x $\frac{1}{2}$ in. Allowing 5 tons per square

SUPPORTING A GALLERY.

inch in tension, the net sectional area of bottom flange would be 11 sq. in.; deduct four $\frac{3}{4}$ in. rivets from width of flange, $15 - 3 = 12$ in. wide. Therefore, thickness equals $\frac{11}{12}$. Therefore, say two $\frac{1}{2}$ in. plates 15 in. wide. Web $\frac{3}{4}$ in. thick. The section of girder would be as shown in Fig. 1; the general arrangement as Fig. 2; Fig. 3 is the elevation. HENRY ADAMS.

Deductions from and Payment of Rates, &c.

MASHAM, YORKS.—COLLECTOR writes: "(1) Where owners pay the rates of cottages valued under £8, can they claim 15 per cent. deduction from highway rate and 20 per cent. from rates for general district and lighting purposes? For instance, fifty cottages have altogether a gross ratable value of £250, and a net value of £208 6s. 8d., which at 1s. in £ is £20 16s. 4d. Am I only entitled to collect £17 13s. 8d. highway rate, and £16 13s. 1d. general district rate? (2) For general district purposes, where the occupier of plantations is also owner, are such plantations liable to be assessed at only a quarter ratable value? (3) If I meet a ratepayer in the street or on the highway and I suggest to him or ask him for a certain rate or rates due from him, and he refuses to pay; and on such refusal I offer him a demand note for the rate or rates there and then, which he refuses to take; does such an offer and refusal constitute a legal demand for such rate or rates?"

(1) It appears that the deductions which you specify must be made. See section 211 of the Public Health Act, 1875. (2) Yes. See the above-quoted section. (3) It appears to do so, but you should be able to prove having made the demand. G. H. B.

Utility of Becoming an A.R.I.B.A. or M.S.A.

EDINBURGH.—T. G. J. writes: "I have just completed my fourth year as pupil to an architect here, but have not as yet sat for any examination, such as the A.R.I.B.A. From enquiries made, I am led to understand that the possession of this qualification does not carry so much weight with architects in Scotland as it does in England, where, to practice successfully, I am told it is almost indispensable to hold it. Circumstances make it rather uncertain where I might eventually start business for myself. Do you think it would repay me to commence studying even now for this examination, considering that I am through my apprenticeship? Also, are there any other qualifications besides the A.R.I.B.A. which an architect may take with advantage, and how long would the courses of study involved occupy?"

Whatever detractors may say to the contrary, it is well worth the necessary effort to take up Associateship of the R.I.B.A. The course of training is lengthy and severe, but the gain to every man who conscientiously goes through it is commensurately great. It is not the value of the qualification in the eyes of the public which is of most importance, but your own enhanced knowledge and the feeling and

actuality of strength which this gives. Membership of the Society of Architects can be obtained after passing a single examination, which is in most ways equal to that for Associateship of the R.I.B.A., and in some respects superior. The secretaries of each of these bodies should be written to for details. Address: Secretary R.I.B.A., 9, Conduit Street, W.; and Secretary Society of Architects, St. James's Hall, Piccadilly, W. G. A. T. M.

Damage to Highway by Overflow of Beck.

MASHAM, YORKS.—SURVEYOR writes: "On two distinct occasions during the last three months a district highway has been damaged to the extent of about £25 by the overflow of the beck when in flood. The water leaves the beck whilst in fields occupied by various tenants and owned by one landlord, who is also lord of the manor, and from the fields it flows on to the road, washing off the metal, &c. (1) Can my Council (urban district) on the report of the surveyor recover from the landlord the damage done? (2) Are the tenants liable for such recovery, if the landlord by agreement has let the said fields for tenants to repair watercourses? (3) Where no written agreement exists, is landlord liable? (4) Can the Council compel either the landlord or tenant, as the case may be, to widen to a prescribed width, and embank to a certain prescribed depth, the bed of the beck in question? (5) In cases where accommodation bridges over the beck are too small to allow the uninterrupted flow of the water, can the Council enforce either the removal or enlarging of these bridges, when such interruption causes the water to flow over the fields on to the highway? (6) Where water rails are a source of interruption, can the Council compel

that they shall be so hung that the water can flow without interruption from them in flood time?"

(1) Yes, except in the case of an extraordinary flood, which might be held to be an "act of God." (2) It appears that the landlord is primarily liable to the local authority; but it has been held that, for purposes of the Highway Acts, the term "owner" includes the occupier, even if a yearly tenant (see *Woodward v. Billericay Highway Board*, 11 Chan. Div. 214). (3) Yes. (4), (5), (6) Yes, apparently. G. H. B.

R.I.B.A.

AT a special general meeting of the Royal Institute of British Architects held last Monday evening at eight p.m., Mr. William Emerson, president, in the chair, Professor the Commendatore Rodolfo Lanciani, Correspondent de l'Institut de France, D.C.L. Oxon., Hon. Corr. M. of the R.I.B.A. at Rome, was elected the Royal Gold Medallist for the current year. At the conclusion of this special general meeting a general meeting (business and special) was held. The minutes of the previous meeting having been read and confirmed, the following were elected members of the Institute:—As Fellows: Messrs. David Barclay Niven, William Edward Riley and Herbert Hardy Wigglesworth, all of London. As Associates: Messrs. Francis Henry Allen, of Northampton; William Henry Ansell, of London; Spencer Ellwood Barrow, of Lancaster; Francis William Ashton-Buckell, of London; Thomas Joseph Byrne, of London; Miss Bessie Ada Charles, of London; Messrs. David McLeod Craik, of London; Alfred Herbert Foster, of London; Frank Foster, of London; Stanley Hinge Hamp, of London; John Harry Woodall Hickton, of Walsall; Mathew Honan, of Liverpool; Herbert Edward Illingworth, of Leeds; Alfred Ralph Keighley, of Liverpool; Thomas Anderson Moodie, of London; James Edward Coleman Shield, of London; John Edward Spain, of Wragby; Reginald Henry Spalding, of London; Frederick Taylor, of Aylesbury; Ramsey Traquair, of London; Thomas Tyrwhitt, of London; and Harold Watts, of Plymouth. As Honorary Fellow: The Right Honourable Sir Richard Temple, Bart., G.C.S.I., C.I.E., D.C.L., LL.D., F.R.S.

A further special general meeting was then held, and adopted the following recommendations of the Council, moved by the chairman: "(1) That in By-law 25 the words 'thirty-six' in the first line be altered to 'thirty-eight,' and that the word 'two' in the second line of section (a) be altered to 'four.' (2) That in By-law 29 the second sentence be altered so as to read, 'Any Associate shall be eligible to serve as an Associate-Member of Council.' (3) That in By-law 30 the word 'three' in the seventh line be altered to 'six,' and further that the words 'but the names of members of the existing Council shall be distinguished by an asterisk,' be omitted from the same By-law." The meeting then terminated.

Mr. G. F. Watts, R.A., who recently reached his eighty-third birthday, though one of the oldest of living painters, is fourteen years the junior of Mr. T. Sidney Cooper, who was elected to full membership of the Royal Academy in the same year, 1867. Mr. Watts is of Welsh descent and was born in Herefordshire. He first exhibited at the Royal Academy in 1837.

A Proposed Liverpool Improvement.—Since the demolition of St. John's Church a proposal has been made and found much favour that the site should be utilised for the erection of the statue of Mr. William Rathbone, and a further suggestion is that St. John's Churchyard should also be ornamented with the statues of Mr. Gladstone and Sir A. B. Forwood. Mr. George Frampton, R.A., sculptor, who has been commissioned to execute the statue of Mr. Rathbone, has also prepared a model for the laying out of St. John's Churchyard.

Professional Practice.

Bulwell, Nottingham.—A new reredos has been erected in the parish church of Bulwell. It is executed in alabaster, in the Gothic style. The higher central portion contains a representation of the Crucifixion boldly sculptured within a richly traceried, crocketed, and ogee-shaped arch. Underneath, in raised gilded letters, are the words "God so Loved the World." On each side of the central arch are traceried niches, one containing a figure of St. Paul and the other St. Peter. The arches are divided by moulded buttresses, terminated with carved pinnacles. The wall on each side of the reredos is covered with polished alabaster low panelling, arched and traceried, and surrounded with carved cornices. On the south wall is an alabaster tablet, bearing the following inscription:—"To the glory of God, and in affectionate memory of Thomas Hardy, of Bulwell Hall, esquire, the reredos was placed in this church of St. Mary the Virgin, by his widow and children, in the year of our Lord 1900." The work has been executed by Messrs. Farmer and Brindley, of London, from the design and under the direction of Messrs. Heazell and Son, architects, of Nottingham.

Wakefield.—The opening ceremony will soon take place of the new acute hospital in connection with the West Riding Asylum at Wakefield. It has cost £90,000. The buildings have been in course of erection for the past three years, and, including the grounds connected with them, cover about seven acres of ground. The West Riding Asylums have for some time past been in a congested state, and at the present moment the County Council is engaged in providing a retreat for private cases of insanity at Scalebor Park, and is about to erect an asylum at Storthes Hall, near Huddersfield, to provide accommodation for 2,000 inmates. Mr. Vickers Edwards, the West Riding architect and surveyor, is making good progress with the plans for the Storthes Hall Asylum, and the building at Scalebor Park is at present in course of erection. The plans for the new acute hospital were prepared by Mr. Vickers Edwards, and the work has been carried out under that gentleman's superintendence by Mr. Isaac Gould, of Hartshead Works, Hunslet, with Mr. John Maclaren as clerk of the works. The buildings, which are of red brick, with stone facings, occupy a commanding position at Field Head, a short distance from the Wakefield Asylum, with which they are connected and which they overlook. They are also in close proximity to Stanley Hall, which was recently purchased by the County Council and is at present being repaired and altered in accordance with plans prepared by the county surveyor, and at an additional cost of £2,000, for the purpose of providing accommodation for about sixty male idiots under eighteen years of age. One end of the new building is divided from Stanley Hall by the Wakefield and Aberford Road; the other end adjoins the private road leading from Field Head to the old Asylum, and is fenced in with a substantial brick boundary wall with stone coping. Externally, the buildings are not very ornamental. In regard to the cost, it may be stated that (not including the land) it will be equal to about £335 per bed. This, to some persons, may appear a large sum, but in several ordinary asylums in this country the cost has exceeded £400 per bed. At the rear of the hospital are two cottage homes, one for thirty-six females, and the other for a like number of male patients. These will be occupied by patients who are considered fit to engage in domestic work. There are certain other small and detached erections at the rear to be utilised for various purposes. In the course of a few years these will be screened from view, as a plantation has been formed, and a thick belt of trees will be seen later. The extensive grounds in front of the buildings are being tastefully laid out and planted with suitable trees and shrubs. A fine, broad carriageway

is being formed between the asylum and the new buildings.

York.—The new electric light works erected by the York Corporation at Foss Island have been opened. The total cost of the installation up to the present has been £20,000. The site of the works is well adapted for the purpose, being close to the river Foss, whence it is possible to obtain a good supply of water for condensing and steaming purposes. The land around the works is also the property of the corporation and will permit of large extensions of the buildings. The design and erection of the buildings and chimney have been superintended by Mr. A. Creer, the city engineer, and the mechanical and electrical equipment has been built and erected to the specifications of Dr. Kennedy, the well-known consulting electrical engineer. The buildings include a boiler house 55ft. by 35ft., containing two boilers, each 28ft. long and of 8ft. diameter. The chimney is 180ft. high, with an internal diameter of 7ft. 6in. at the top. It is capable of serving four times as many boilers as are at present installed. The chimney will also be used for the refuse destructor, on which a start has already been made. It is expected that the heat generated by the burning of the refuse will in its turn generate sufficient steam to take the day load of the electric light station, if the steam is not required for other purposes. The engine room contains four engines and dynamos, and the number of 8 candle-power lamps which can be supplied with current from the dynamos at any one time is about 6,600. The storage battery consists of 250 cells, and is situate in a room 47ft. by 16ft. The original scheme provided for distributing cables being laid in Coney Street, Spurrier Gate, High and Low Ouse Gate, Lendal, Museum Street, Blake Street, New Street, Market Street, Fease Gate, Clifford Street, St. Leonard's, Goodram Gate, and Parliament Street; but it has been found desirable to extend the mains owing to the number of applications received, and already extensions have been run down Pavement and Foss Gate, and up Mickle Gate to the Mount. The price at which the current is supplied is arranged on what is known as the rebate system—that is to say, the consumer is charged 7d. per unit on the first 182 hours' consumption, and 3d. per unit on all the remaining consumption per half-year. The contractors for the station were as follows:—Messrs. Parker and Sharp, York, for the buildings and chimney; Messrs. Crompton and Co., London, for the whole of the machinery; and Messrs. Callender and Co., London, for the mains.

Stainland Wesleyan Chapel has been renovated at a cost of £2,000. With the exception of the entrances and staircases, the interior has been entirely remodelled, and seating accommodation is provided for 550 persons. The architect was Mr. J. Berry, of Huddersfield. A new organ has been supplied by Messrs. A. Young, of Manchester, at a cost of £450.

Proposed new Fire Station at Birmingham.—At a meeting of the Birmingham Watch Committee on February 27th the report of a sub-committee recommending the erection of a sub-fire station at Saltley at a cost of £7,300 was adopted. The land for the station is at the corner of Lingard Street and Saltley Road, and the plans provide accommodation for a machine room, 31ft. by 36ft., stables for four horses, and usual offices. Quarters are provided for an engineer, eight married men and their wives and families and a number of single men, and sliding poles are provided to facilitate access to the engine house.

WERE YOU EXCITED when the news of the relief of Ladysmith was received? At any rate you no doubt shared in the general rejoicing, and in case you wish to make a thank-offering, we would point out that the **B.J. Shilling Fund** is still open.

New Patents.

These patents are open to opposition until April 7th.

1898. — Cement Manufacture. — 27,431. J. HASTIE and J. GILL; both of Edinburgh. The raw materials are ground in a mill to pass through a $\frac{3}{16}$ in. mesh. They then fall automatically into a drum containing a heavy edge-runner and a series of elevators or mixers; here the materials are thoroughly mixed and reduced to pass through a mesh of 2,500 holes to the square inch. In this ground state they are next sucked out by air into a collector having the form of an inverted cone, from which they are conveyed by chain buckets to a machine to be pressed into blocks for burning. Any degree of fineness can be obtained by varying the air suction.

1899. — Sewage Filtration. — 2,461. D. CAMERON, F. J. COMMIN, and A. J. MARTIN; all of Exeter. This invention is designed for the purpose of introducing air into sewage, or, preferably, into the effluent from a septic tank. The sewage is passed through a chamber into which water, or wholly or partly clarified sewage, is showered. Air is taken down in this way. Frays of coke and partition walls built of perforated bricks may be used to hold the air. An improved junction between the distributing and main channels forms the subject of another part of the invention.

Cork Flooring or Paving. — 2,800. F. BARTLETT, Bury. Powdered cork is made into a composition with an adhesive; for instance, $\frac{1}{2}$ lbs. of shellac, dissolved with $\frac{1}{2}$ lb. borax and $\frac{1}{2}$ gals. of water, are added to every 1 cwt. of granulated cork. The composition is then dried, and afterwards moulded. It is next pressed and heated to between 200 deg. F. and 300 deg. F. It is then cooled.

Blind Rollers. — 3,988. J. S. SMITH, Sale. — In a dovetail groove in the roller fit two lips, which clamp and hold the blind in place.

Facing Walls. — 6,217. D. SWANSON, London, W. Screwed studs are built in the wall with their ends projecting slightly. Facing sheets of, say, plaster of Paris, having a backing of hair felt, are placed against the ends of the studs, and held there by boards that are secured by means of ferrules screwing in the studs. The space between the back of the facing sheet and the wall is then filled with coarse stuff. The work is done in sections, and, when finished with, the boards, &c., are removed and the holes filled up. The plastering can thus be completed in one operation.

Exhaust Steam Heating Apparatus. — 714. T. J. CODD, Leytonstone. The exhaust steam is conveyed in a main leading to the atmosphere, a balanced non-return or flux valve being arranged at a convenient point. Branches are taken off to the radiators. This arrangement minimises back pressure.

Partition Walls. — 6,924. J. CHAPMAN, Cambridge-on-Tyne. The walls are formed of plaster slabs having cores through them and being interlaced with wire netting, which are supported by vertical and longitudinal wires or bars.

Casting Cement Pipes. — 18,353. C. J. MELBERG, Copenhagen. This invention is characterised by a drum, placed in the mould and forming the core. On the outside it has spiral projections by means of which it is screwed up, compressing the pipe and making it smoother.

Ceilings. — 24,948. R. B. RANSFORD, London, (The Basel Mission Tile Works, India). Solid hollow slabs of burnt clay are supported on ceiling rafters by means of mouldings of burnt clay that are slid over battens on the rafters, and held in place by nails.

The following specifications were published on Tuesday last, and are open to opposition until April 14th. A summary of the more important items will be given next week. The names in italics within parentheses are those of communicators of inventions.

1898. — 25,917, BEGGS and FIELDING, apparatus for the manufacture of acetylene gas.

1899. — 873, REDMAN, atmospheric gas burners. 2,441, THOMPSON and THOMPSON, valves for stopping or controlling the passage of steam or water. 2,506, JAMES (American Stoker Co.), method of and apparatus for making gas for heating purposes. 2,598, FREW-WEST, back rests for chairs and other seats. 3,023 HAWKINS, acetylene gas generators. 4,255, WINDHAM, acetylene lamps. 4,636, EVANS, acetylene gas generators. 5,107, SUGG, radiators for heating buildings. 5,210, DEFRIES, door bolting mechanism. 5,211, MILLER, electric incandescent lamps. 5,415, NOTON, filters used for the purification and filtration of sewage and for treating water for domestic purposes. 5,867, TALBOT, lanterns for incandescent gas lighting. 6,174, BURTON, locks and latches. 6,185, HECKFORD and BAGNALL, latch bolts. 6,799, MILLAR, combination tools. 6,905, HUGHES, intercepting or disconnecting traps for drains and sewers. 6,968, EDMONDSON, securing door handles or knobs on their spindles. 7,217, SMITH, hot-water boilers. 7,318, GRAYSON, fire extinguishing apparatus applicable as a fire escape. 7,403, HAWKIN, device for cleaning windows. 7,452, BENSON, bracket for window-blind rollers. 8,383, BANKS and BANKS, manufacture of door bolts. 10,416, MENGARINI, incandescent electric lamps. 10,505, MOTT, blowers and draught regulating appliances for open stoves. 12,340, RAU, steam heating apparatus and condensing or cooling apparatus. 13,095, LOVELAND, window blinds. 20,211, NOAD, method of preparing decorative surfaces. 20,323, MARKS (Murphy), gas engines. 21,589, LORME (Decayaux), door, or other locks. 21,615, BRITISH THOMSON-HOUSTON CO. LIMITED (Fleming), electric arc lamps. 23,714, SCHULZ, screw lifting-jacks. 23,760, DE REDON, nut-lock. 24,824, HOWARD, electric incandescent lamps. 24,828, LINCKE, adjustable device for suspending and fixing lamps. 24,878, THOMPSON (Gallassi and Dossani), vapour lamps for incandescent lighting. 25,140, EDWARDS, fixing and connecting railings in panels and to standards. 25,459, BREMNER, self-sustaining device applicable to elevating machines and cranes.

Under Discussion.

Workmen and Workshops.

A paper on "Health in the Workshop" was recently read by Mr. J. D. Sutcliffe before the Manchester Association of Engineers. The lecturer explained particulars gained in the last eighteen years, during which period he had inspected workshops and factories in all parts of Europe. He condemned the attitude of firms who were content to plod along in the unsuitable workshops of fifty years ago, and maintained that we had to-day in this country workmen who could not be excelled in the whole world when their energy and skill were properly directed. He instanced the work at the Rylands Library. In Canada and America much more attention was paid than with us to the cleanliness and healthfulness of the factory. The principal difficulty in getting good ventilation and warmth was the cost. In America it was not uncommon to pay 20 to 25 per cent. of the total cost of a building for adequate warmth and fresh air. How different was this from the allowance of an English architect of £5 for a "cow" to be fixed on the roof by the builder where the cost of the building had been £5,000! Good ventilation and warmth in the long run would actually pay better than many other things considered essential in all well-designed workshops. With regard to "natural ventilation," he said that on factories and workshops the best outlet was the louvred wooden turret. Many difficulties disappeared if fans were used. The amount of air required was obtained simply by choosing the right size of fan and driving it at the proper speed, and then the only problem lay in the proper distribution of the air. The difficulty with air currents was in controlling their direction. Mr. Sutcliffe commended the double duct system of combined warming and ventilating — one that was in use at the Salford Technical

School. He showed illustrations of a factory in Dayton, Ohio, where there is not only a wage list of £200,000 a year, but each year "a sum of £50,000 is appropriated for the realisation of what are called Utopian ideas." The proprietor was described as "neither a poet nor a prophet," but a manufacturer who looks with contempt on philanthropy and values only what is practical. He had said: "Everything that makes my employee a better man gives me through him a better piece of work. It is never a question therefore whether to spend money for his benefit, but only how to spend it to increase his knowledge, his happiness, or his health. Money spent to produce such results will bring as quick and sure a return as that invested in any other of the more customary ways of developing a business."

Scotch Ecclesiastical Architecture.

Mr. Thomas Ross delivered a lecture on the "Ecclesiastical Architecture of Scotland from the Twelfth to the Sixteenth Century" in the hall of the National Portrait Gallery, Edinburgh, on February 26th. Mr. Ross pointed out that the earlier developments of the Gothic style of architecture coincided with the period of the Norman invasion of England, while the new era began in Scotland with the marriage of Margaret, sister of Edgar Atheling, to Malcolm Canmore. The Celtic Church gradually disappeared, and the Roman Church took its place and became the great power in the country for the next five centuries. Religious establishments on a scale of size and grandeur not hitherto dreamt of in Scotland arose on all sides — cathedrals, abbeys, and parish churches, whose ruins constituted what we now called the Norman ecclesiastical architecture of Scotland. It was under David, however, that the enthusiasm for church work reached a height which was probably not surpassed by any contemporary sovereign. After dealing in detail with some of the architectural remains of the earlier period, Mr. Ross expressed his scepticism in the general belief that the existing nave at Dunfermline was part of the church built by Margaret. Most advanced and most perfect preparations, he said, were made for ribbed vaulting, such as had been made nowhere else in Europe in the year 1074, and this consideration alone would convince any archaeologist that the nave was not a part of Margaret's church. There were at least seventy-five places in Scotland which had indications remaining of having had churches in the Norman style. Apart from abbeys, churches, or cathedrals, they were aisleless structures, the church of Rutherglen being an exception. It was quite possible and probable that the ancient rivalry between Rutherglen and Glasgow, which existed in the twelfth century, might have found expression in the erection of a church in the King's burgh to rival in architectural splendour that of the bishop's burgh, or it might have been the opposite way — the church at Rutherglen might have incited the bishops to outdo it. Be this as it may, the church at Rutherglen was a building of considerable importance.

Recent Excavations in Greece.

Mr. Charles Waldstein, Litt.D., Ph.D., L.H.D., Slade Professor of Fine Art at Cambridge, gave last Thursday the first of a series of three lectures on "Recent Excavations at the Argive Heraeum, in Greece." The site of the sanctuary of Argive Hera (Juno) he described as lying on the north-eastern side of the beautiful Argive plain, between the ancient cities of Mycenae and Tiryns, and opposite the city of Argos. This sanctuary was one of the most famous in ancient Greece, and was specially notable as containing the great gold and ivory statue of Hera (Juno), a work of the great sculptor Polykleitos, of Argos, second only to Phidias, whose contemporary he was. This splendid sanctuary was classed by the ancient authors with the two greatest sanctuaries in Attica and Elis, namely, the Parthenon and the Temple of Zeus at Olympia. The sanctuary was discovered accidentally, in 1831, by General Gordon, of Cairness, who made some tentative excavations in 1836, which were followed by further tenta-

tive excavations by Rhangabé in 1854. The whole of the site was finally excavated by the American Archaeological Institute and School of Athens, under the direction of the lecturer, from 1892 to 1895. From a description of Pausanias they were led to expect remains of the great temple, built in the fifth century B.C., and traces of the destroyed earlier temple, built before the "Homeric Age" and burnt by the negligence of the priestess Chrysis in 423 B.C. Not only did they have the good fortune in the excavations to come upon the whole of the second great temple of the fifth century B.C., but to reveal traces, on the upper slope, of the earlier temple, spoken of by Homer as the temple of Hera. Traces of the conflagration were found and the whole pavement of this early temple was unearthed. Below the foundations and in various regions of this site were indicated traces of a civilisation which preceded the erection of this temple, leading back by facts, not by mere inferences, to a period 2,000 years or more before Christ. From these early beginnings there was an uninterrupted chain of evidence through the greatest Hellenic periods down to Roman times and later, the examination of which would convince anyone that the study of archaeology and antiquity, sometimes regarded as a dry-as-dust sort of study, was full of supreme poetry, and could bring back to us the past more vividly than any other study could do. Dr. Waldstein then proceeded to describe and explain a series of lantern slides illustrating the various stages in the excavations. He stated that of the second temple, built by Eupolemus about 420 B.C., considerable remains were found—sufficient to enable a complete architectural restoration to be made—while higher up the hill, which before excavations were commenced looked like an ordinary hillside sloping down to the plain in an unbroken roll, the polygonal pavement of the upper temple was discovered, together with portions of the wall, so that the outline of its plan could be determined and even a fair restoration of the structure itself made possible. Views were also shown of the Cyclopean foundation walls on the upper platform, with their huge stones 18ft. long; of a building, probably a gymnasium, dating from the end of the sixth century, the ground plan of which was clear on the south-west of the site; of a colonnade, with the remains of some columns still existing, from which a long marble staircase led up to the second temple; of a kind of propylæum of the Mycenaean period, and of several other buildings. Altogether, nine buildings belonging to various periods, in addition to the later temple, were found within the sanctuary.

Messrs. R. Waygood and Co. have been commanded to provide the royal yacht Victoria and Albert with a passenger lift for the exclusive use of her Majesty the Queen.

Mr. John Giles, senior partner in the firm of Giles, Gough and Trollope, architects, of 28, Craven Street, Strand, died on February 20th in his sixty-fifth year. Mr. Gough joined the firm in 1872, and Mr. Trollope in 1886.

Enlargement of Wakefield Cathedral.—At a meeting of the Walsham How Memorial Committee on Friday last, the contract of Messrs. Armitage and Hodgson, of Leeds, for the enlargement of the Wakefield Cathedral was again considered, and it was decided to ask them to execute the work throughout in Netherton stone. Their estimate for building the crypt and two vestries under a separate contract was approved. The estimate for the crypt works out at £8,842, whilst that for the whole of the building stands at £25,100. The contractors will enter upon their work on the 19th inst., and they undertake to complete the first portion (the crypt and vestries) in about eighteen months. The second portion (the whole of the work, if continued under one contract) will be completed in September, 1902. A sub-committee recommended that a design by Mr. Forsyth, of London, the eminent sculptor, of a recumbent effigy of the late Bishop Walsham How, should be accepted, and their recommendation was adopted. The cost of the effigy will be £750.

Keystones.

Artists' War Fund.—The proceeds of sale of the pictures recently on exhibition at the Guildhall amount to £9,120 8s.

St. Dunstan's Church, Stepney, is being restored by Messrs. J. E. and J. P. Cutts, architects, of Southampton Street, Strand.

Ruskin's Description of Giotto's Frescoes at Padua has been republished by Mr. Allen. The original book appeared in 1854.

At St. Peter's Church, Eastbourne, a new side chapel has been erected at a cost of £1,500. A new altar, costing £200, has also been provided.

The Death is announced of Mr. Andrew White Tuer, the well-known Fellow of the Society of Antiquaries and manager of the Leadenhall Press.

Mr. William Stott, of Oldham, the well-known artist, died recently at sea in the course of a short voyage undertaken for the benefit of his health.

St. Mary's Church, Plaistow, Bromley, is about to be enlarged according to the designs of Messrs. Wadmore and Mallett, architects, Chancery Lane, W.C.

The Grand Theatre, Islington, was almost entirely destroyed by fire last week. The fire was due to the "avalanche" in "Hearts are Trumps" being scattered by a slight gas explosion and set alight.

Hanover Square Rooms, W., once so fashionable, will soon cease to exist, as the building in which they are situated is to be taken down or converted into shops. The concert room recalls somewhat the glories of its former self.

Blocks of Industrial Schools at Bishopbriggs, Glasgow, are proposed to be built on the Kenmure estate. A site of about seventy acres has been purchased, and it is proposed to erect five blocks, each providing accommodation for twenty children.

New Gates at Kidderminster Parish Church have been erected by Messrs. Hill and Smith, of Brierley Hill; they are of the best Staffordshire wrought iron, hand hammered. There are two central gates and two foot gates, carried by four new massive stone pillars.

Patriotic Archaeologists.—At a meeting last week of the Alcoa Society of Natural Science and Archaeology, the lecturer (Dr. Currie) thought before proceeding to business that three cheers ought to be given for Lord Roberts. This met with an enthusiastic response.

Memorial to the late Duchess of Rutland.—A stained-glass window has been erected in Ilkeston parish church to the memory of the late Duchess of Rutland. It is of three lights and has been placed in the ancient chantry, supposed to have been erected by Joan de Cantilupe about 1360.

Housing Problem.—An international congress on the housing problem is to be held in Paris from June 18th to 21st next. The subscription for a member is 10 francs. Mr. Paul Langer, of 40, Gledstones Road, West Kensington, W., will be pleased to forward a programme to any applicant.

The Official Architects of Paris have been nominated by the Prefect of the Seine as follows:—Chief Superintending Architect, M. Sauger; Superintending Architect for the Eastern District, M. Dardouze; Superintending Architect for the Western District, M. Vigneulle; Superintending Architect (4th class), M. Longfils.

New Chemical Works for Cheshire.—The construction of extensive new chemical works at Cledford Bridge, near Middlewich, has been commenced by the contractor, Mr. Wilson, of Runcorn. The works are for the Electrolytic Alkali Company, whose present offices are at St. Helens. Orders have been given for engines and dynamos, and the total cost is estimated at £100,000. The new works will provide employment for a large number of men.

New Church Schools at Filey have been built in Murray Street at a cost of £1,909.

Statue of the Queen at St. Peter Port, Guernsey.—The bronze statue of the Queen which has been erected in the Candie Ground by public subscription was unveiled on March 1st by the Lieutenant-Governor (Major General M. H. Seward) in honour of the relief of Ladysmith.

"The Undercroft," Southampton.—The Town Council of Southampton have decided to preserve as a memorial of antiquity a fine example of early fourteenth century work known as The Undercroft, which had been threatened with destruction by street improvements under the clearance of one of the older parts of the town.

Home Arts and Industries Association Exhibition.—The sixteenth annual exhibition of the work done in the classes of the Home Arts and Industries Association will be held from May 24th to 28th in the gallery of the Royal Albert Hall. The exhibition will include wood-carving, inlay, metal repoussé, embossed leather, baskets, spinning and weaving, toy making, and many other applied arts. The percentage on sales will be given to one of the war funds for the wounded soldiers.

New Companies.

Great Yarmouth Brick and Tile Co., Ltd.

This company was registered without articles of association on February 13th, with a capital of £1000 in £1 shares.

COMPETITIONS.

BOROUGH of ANDOVER.

The Town Council are open to receive DESIGNS for a CRICKET PAVILION with Lavatory and accommodation for supplying refreshments, &c., to cost from £200 to £300, and offer a premium of £5 5s. for the one selected.

They do not, however, bind themselves to accept any Design sent in.

All Designs must be sent to the office of the Town Clerk on or before MARCH 28th inst., endorsed "Pavilion," and the one selected (if any) is to become the property of the Council.

THOS. E. LONGMAN, Town Clerk.

Andover,
March, 1900.

ADMINISTRATIVE COUNTRY of the ISLE OF WIGHT. TO ARCHITECTS.

The Technical Education Committee of the County Council of the administrative Council of the Isle of Wight invite DESIGNS for a BLOCK of BUILDINGS, comprising a Public Library and Reading Room, Technical Institute Offices, Caretaker's Residence, &c.

A lithograph plan of the site, with sketch showing approximately the accommodation required, and instructions to competitors will be forwarded on application to the undersigned.

The cost of the buildings is limited to about £6,000. Premiums of Fifty Pounds each will be given to the authors of the two Designs considered by the Council as the first and second in merit which designs will become the property of the Council. The author of the Design considered the best shall, if required by the Technical Education Committee of the County Council, furnish the necessary contract drawings, with details, and specification, for the purpose of obtaining Tenders to execute the work, for which, if so required as aforesaid, he will be paid 2½ per cent. on the estimated cost. If employed to superintend the works such 2½ per cent. and the premium of Fifty Pounds to merge in the usual architect's commission of 5 per cent. on the cost, which shall include the necessary detail drawings, copies for contractor and clerk of the works, superintendence, and all expenses.

All designs to be sent, in accordance with the instructions, to the undersigned on or before APRIL 30th, 1900.

WILLIAM H. WOOLDRIDGE,
Clerk to the County Council.

County Council Offices,
Newport,
Isle of Wight,
February, 1900.

Binding Cases may be had on application
to the Manager. Price 1s. 9d. each.

ARTIFICIAL HEATING.*

By W. E. MAGUIRE, J.P., A.I.C.E.I.,
Vice-President Institute of Heating and Ventilating Engineers, London.

HEAT is measured by a standard unit. The B.T.M., or British Thermal Unit, is the amount of heat required to raise 1lb. of water one degree F., say from 50° to 51°. In the metrical system the caloric is adopted as the unit, being the amount of heat required to raise a kilogram of water from 0°C. to 1°C. The foot-pound is the standard English unit of work, and is the amount of work done in raising a 1lb. weight to 1ft. high. Professor Joule fixed the mechanical equivalent of heat as 772 foot pounds; a weight of 772lbs. falling 1ft., or a weight of 1lb. falling 772ft., produces 1 unit of heat; 1 unit of heat, theoretically, should do 772 units of work. One pound of coal is taken to contain, according to quality, from 16,000 to 12,000 units of heat, or, theoretically, from 12 to 9 million units of work in foot-pounds. When applied, a very large proportion of this is lost in radiation, friction, &c.

In artificial heating the heat may be distributed in three ways—by radiation, convection, and conduction. Radiant heat passes in straight lines and at right angles from the heating surface, and travels through air without raising its temperature until the rays strike some heat-absorbing matter. The sun's rays do not warm the air, but they warm the earth, which, by convection, warms the air. The radiant heat rays from a fire, or from any hot surface, also pass through the air of a room without effect, but they warm the floor, walls, ceiling, furniture, which in turn warm the air by convection. Convected heat is that portion of heat which is rubbed off heated surfaces by gases or liquids passing over and in contact with those surfaces; air and water thus take up heat, and by their mobility and power of expansion rapidly convey by direct transport the heat so acquired, and distribute it effectively according to known laws. Conducted heat is only another form of convection. Heat applied at one end of a metal bar will travel by conduction to a distance on that bar, the distance depending on the conductive power, which varies in each metal. Take silver as 1,000, copper 776, iron 119, lead 85, German silver 60. A sheet of silver would be of the least possible use if placed on a wood floor under a hot-air stove; sheet iron would be of some use, sheet lead better, and German silver best, being the best non-conductor.

Much advantage is taken of latent heat in artificial heating. The heat which ice at 32° takes up and conceals, or renders latent at the moment of its conversion into water at 32° under the atmospheric pressure of 30in. of mercury, is called the latent heat of liquifaction; and as 1lb. of ice at 32° takes and conceals as much heat to change it into water at 32° as would be required to raise 142lbs. of water one degree; and as 1lb. of water at 212° takes and conceals as much heat to change it into steam at 212° as would be required to raise 966lbs. of water one degree; the latent heat of water is 142 units, and equals the latent heat of liquifaction; the latent heat of steam is 966 units and equals the latent heat of vaporization. The heat rendered thus latent when water is vaporized into steam is conveyed in the steam to the radiating surfaces, and there the latent heat is again given out during the condensation of the steam to water, and radiated thence to surrounding objects, or rubbed off the heated surfaces by convection and distributed where required.

The greatest amount of heat is obtained from radiators by convection. You can prove this by placing boards on top of a large radiator in any room and checking the flow of air over the surfaces, while allowing free radiation all round, and observing the temperature attained in a given time; then remove the top board and surround the radiator with boards to check radiation, but

leave a space under them for the air to pass freely over the surfaces of the radiator, rubbing off the heat and escaping into the room; and then compare the temperature obtained in the given time with that obtained in the previous case.

How much should an architect know about artificial heating as applied to his buildings? No ordinary mortal architect can grasp all the details of the various arts, sciences and manufactures with which his noble profession brings him into close contact, but he may and ought to have a sufficiently intelligent and practical knowledge of the various artificial requirements of every building he designs so as to be able to define clearly to his clients on the one hand and to his engineer and contractor on the other what those requirements are. He ought to know just enough about heating, ventilating, lighting and other arts to be able to detect and appreciate difficulties when they arise or are created in the elaboration of his plans, so that he may have timely notice when the engineering details are getting beyond his experience and before he gets out of his depth. The aim of this paper will therefore be to indicate and explain the points in the artificial heating of buildings which a well-equipped architect ought to know, rather than to elaborate details belonging to the province of the practical engineer.

Architects should be aware that the cost of effectual artificial heating depends largely on the materials used in building. An iron structure is more difficult to heat than a wooden one. A stone building requires more heating surface than a well-built brick building. Thin and solid walls will waste more heat than thick or hollow walls. Dryness in walls and foundations helps the heating engineer materially. Double-glazed windows effect a considerable saving of heat. The amount of radiating surface should be fixed by the heating engineer, not only by standard formulæ, but by experience. An apparatus continuously at work heating a building satisfactorily might prove quite insufficient if worked only once a week, as is usual in churches. An approximate and very rough estimate of hot-water apparatus, radiating surfaces for heating halls, staircases, and schoolrooms at about 35° in excess of outer air, winter temperature, may be taken at 12 sq. ft. per 1,000 cubic feet of internal space; rooms with one outer wall, 14 sq. ft.; with two outer walls, 16 sq. ft.; with three outer walls, 18 sq. ft.; with four outer walls, 20 sq. ft. Shops usually require about 10 sq. ft., churches and concert rooms, 8 sq. ft. If ventilating radiators are used, add 25 per cent. of surface. Indirect heating requires 50 per cent. additional. The amount of glass, &c., will vary this approximate estimate. In arranging the radiating surfaces you may bear in mind that large surfaces at low temperature give much more pleasant results than small surfaces at high temperature. Temperatures can be reduced by valves at will, but with insufficient radiating surface you cannot increase the heat beyond its limit. The first cost of the radiating surface, too, often curtails it unsatisfactorily.

In this unstable climate, constant only in its inconstancy, we need artificial heating during seven months of the year. You will admit, however, that, though artificial heating is so important a matter, it is often the last and the least considered portion of the plan. Many churches exist in this country without a proper chimney flue and without a suitable furnace chamber, with the result that both inside and outside of such edifices we often find them marred with iron smoke flues of soil-pipe construction. America is famous for its variety of hot-air furnaces. No nation has ever practically experimented to such an extent with these appliances, and no nation can show such a collection of young people prematurely aged, and faded men and women who, in their youth, were remarkable for the purity and brilliancy of their complexions. All heating engineers of standing and wide experience in America or in England agree that artificial heating by hot-air furnaces has many faults and dangers, and only in places where health is considered of less importance than the first cost of the heating apparatus

will this system force itself into prominence. When hot-air furnaces are adopted they are often too small, with the result that in cold weather they are forced to a red or white heat, most injurious both to the apparatus, the air and the inmates of the dwelling. The volume of air passed over the furnace is frequently restricted too much, and care is not observed in taking the air from a pure source; drainage air is sometimes drawn in, heated, and served out again. These are special points to which the close attention of the architect should be directed, as it is very usual for inexperienced and unreliable contractors to fix apparatus of this class cheaply and carelessly, so there is more danger of getting scamped, ill-planned work than with steam or hot-water apparatus.

The danger of setting fire to buildings with overheated furnaces and flues also calls for this special, personal caution of architects in connection with such apparatus.

With hot-air furnaces the heat is sometimes difficult to control, and in many buildings, owing to changes in the direction and force of winds, there results an alternation of hot and cold blasts, the introduction of dust, the burning injuriously to health of organisms floating in the air, wasteful consumption of fuel, and the escape of dangerous gases of combustion into the building. In spite of all these drawbacks, hot-air furnaces are used extensively, owing to their cheapness in first cost and easy rule-of-thumb application. In dwellings or in rooms where inmates sit for hours together the constant breathing of artificially burned or dried air must prove injurious, and in any buildings where long flues capable of collecting and holding dust and dirt would be needed to convey the hot air to given points, let me advise you to beware of recommending hot-air furnaces for adoption. But in churches, where people congregate for brief services, in shops or buildings where constant changes of air occur through frequent coming and going, opening and closing of doors, hot-air furnaces are adopted as a cheap method of artificial heating. In all such cases be very particular to secure a furnace of thick metal, or one with metal sides protected by firebrick, easily replaced when burnt out. See if arrangements are provided for drawing the air of the building itself through the furnace chamber, that you also have an arrangement to stop such draught when the people assemble, and to draw large volumes of fresh pure air from outside through the furnace chamber into the building. The best arrangements of hot-air furnaces are those placed in brick-walled and arched chambers sufficiently spacious to allow free access round the furnace for cleansing and examination. The radiant heat from the furnace heats the walls and roof of the chamber, and the flow of fresh air in passing rubs off the heat rapidly from all these highly heated surfaces, and if it passes at once into the building, and not through prolonged passages and tubes to distant points, a sufficiently satisfactory result may be obtained in churches and concert rooms. The heating chamber must always be right under the body of the building and well inside the outer walls, to ensure steady results with all directions of wind. If the furnace is placed in a chamber outside the walls, such as might be perfectly suitable for a boiler pit, you may find when a strong wind blows against the opposite side of the building that the air inside is forced back through the furnace chamber, reversing its course; so that you must wait until the whole of the parish outside is warmed before you get any warm air into the building, or wait until the wind blows in the opposite direction.

Steam and hot-water heating is now displacing hot-air apparatus in all good buildings in America. We have used high- and low-pressure hot water for heating buildings in this country, and now low-pressure steam from 3lbs. to 10lbs. is in use here. The simple cause of the circulation of hot water in low-pressure apparatus is gravitation. Imagine any ordinary hot-water heating apparatus duly filled, with a flow pipe rising from the top of the boiler, running any distance, and then dropping back into the bottom of the

* A paper read before the Architectural Association of Ireland on February 20th, 1900.

boiler. If all the drops of water in the apparatus are maintained at one temperature, at, say 50°, both in the flow pipe and in the return pipe, each drop will be drawn down towards the centre of the earth by an equal force; in other words every drop will have the same exact density or weight, and so long as that state of things continues there will be nothing to cause any movement among the drops, and the whole body of water will remain in equilibrium and no circulation will take place. Gravity is pulling down the drops of water in the flow pipe with the same force as it is pulling down the drops of water in the return pipe.

Now apply some coal to your boiler and light your fire; the instant that heat is conveyed to the nearest drops of water they stretch and expand, and therefore become lighter drop for drop, bulk for bulk, than the drops in the return pipe. Gravity is quietly acting all this time on every atom of every drop of water in the system, and the instant that some drops expand the force of gravity has less power than before upon the expanded drops, and rather lets them go a little, loosens its hold, whereupon the drops in the return pipe yield to gravitation, and are pulled down, displacing and pushing up the lighter drops. These drops then become heated one after another, and are in their turn pushed up, and circulation starts and proceeds till all the drops in the flow pipe, still cold, press up the warm drops until the circulation becomes faster and faster as the heat increases in the flow pipe, making it lighter bulk for bulk; the water in the return pipe is always cooler, as the heat is given off from the radiating surfaces to the building, and therefore the water in the return, always being more dense, gives the force of gravity greater power upon it to drag it down and so to force the lighter and hotter column up; and so long as the coal dispenses its heat by combustion in the right position so long the equilibrium is destroyed, gravity pulls stronger on the heavier column, and the circulation goes on, giving out by artificial radiation and convection the heat which we desire to distribute in our building. Bear in mind always, for this is important, that the actual difference in the density of the hotter and cooler columns only yields a force of a very few grains in any apparatus, and all obstructions to circulation should, therefore, be avoided.

Low-pressure hot-water apparatus has the great advantage of absolute safety in use; the temperature seldom rises beyond 200°F, and steam is, therefore, never formed under pressure. The apparatus is open at one or more points to the atmosphere for expansion, and the air cannot be injured by overheating or burning. The furnace can be controlled easily by unskilled men, and the fires burn long without attention or renewal and yield economical results, and the temperature remains constant in the pipes and radiates heat equally. The recent great improvements in design and construction of radiators renders the system increasingly suitable for all kinds of buildings. Sections can be arranged so as to be completely shut off, and each radiator can have its temperature regulated at will, which is not the case with ordinary steam heating. Care is necessary in laying out the various circulations to avoid short circuits, dips, air locks, and other obstructions; friction of pipe surfaces on the water flowing, especially at bends, and other changes of direction of flow have a definite retarding effect on circulation. This should limit the extent and range of every hot-water system, for if you go on extending the length of piping in any installation you will reach a point where friction alone will cause circulation to cease, and thus render the system useless. The overhead system of circulation, by which all the hot water is taken by one large flow pipe direct from the boiler to the upper attic floor and is thence dropped in distributing pipes through the radiators on the various floors, has the advantage of increasing the speed of circulation and in removing pipes from the basement. In long range buildings like lunatic asylums, hospitals, &c., several short circulation systems, with boilers for each, will

work more advantageously than one central boiler with long circulations, owing to the obstruction to circulation from friction. But as steam boilers are always necessary in such institutions, low-pressure hot-water heating can be also arranged in short circulations through the various wings with calorifier attached, which may be described as secondary boilers heated by internal steam tubes under high-pressure steam from the central steam boilers; the circulations of hot water through the various sections being induced on precisely the same principle as in the case of the apparatus connected to boilers with furnaces underneath. The writer has also used special steam injectors to heat and drive water round the circulation systems by steam; injected directly under pressure. This steam-injected low-pressure hot-water system is especially serviceable in long circulations, and overcomes one of the difficulties referred to where dips in pipes are unavoidable. This system should not be recommended in buildings where a special steam boiler would be required for the purpose of injection; but in buildings where steam boilers with abundant reserve of steam power are existing for laundry or cooking appliances the system may prove very effective. The objection to steam injectors has hitherto been the noise they cause, which in some cases is unbearable. There is an injector now made which can be fixed to act almost silently, and it is so easily controlled that, by turning a lever handle, heating combined with very rapid circulation starts instantly. In one case where a long circulation previously required four hours to heat partially, this injector did the work effectually in one hour.

The system can be applied to any hot-water system where steam under sufficient pressure can be obtained. The old boiler may be left untouched and ready for use in the event of steam being shut off or unavailable, or it may be taken away altogether. The condensed water from the steam injector mingles with the water in the apparatus, adding gradually to its bulk and overflowing at the supply cistern, whence the hot water is conveyed back to the boiler feed-tanks. In buildings where the circulation of hot water is sluggish and unsatisfactory the system of steam heating by injection should be remembered.

Horticultural buildings are now, and probably will always be, most effectively heated by low-pressure hot-water pipes of 4in. diameter, with about 180° F. average temperature. High-pressure hot-water and steam heat is unsuitable for plants, not only because the heat is too great, but also because temperature rises and falls rapidly as the furnace is brisk or dull. The large volume of water retains its heat for a comparatively long time, even if the furnace is neglected, and neither the air nor the plants suffer from overheating.

Artificial heating by hot water under high pressure in wrought-iron pipes, usually of 3in. bore and 1½in. external diameter, has been in use for sixty years, yet it is not fixed by many firms, as it demands special experience, special workmen and special tools. The pressure and the temperature of the pipes depend mutually on each other. If the pressure is high the temperature is correspondingly high. Apparatuses are constructed to work at pressures from 30lbs. per square inch up to 1,000lbs. per square inch; the pipes are usually tested to 3,000lbs. and the apparatus when fixed complete should be tested to 2,000lbs. per square inch. The apparatus and boiler is formed of one unending coil of pipe; the boiler portion is coiled round the furnace and encased in brick-work or iron, and thence the hot water circulates with great rapidity through the system, and would burst the pipes unless a valve or an air tube were provided to allow for the expansion of the water—this is a necessity. Owing to the great pressure which has to be met, the joints of the pipes must be very strong; no cement has been found capable of resisting the pressure, and the only safe method is to prepare the ends of the pipes at each joint by tapering one end to a sharp edge and by facing the other end dead flat and forcing the sharp edge solid into

the flat end by means of right and left-threaded screws and screwed socket, actually burying one end solid into the other. This requires special tools and specially competent workmen, and such work should not be entrusted to any other. The cause of circulation in this system is the same as in low-pressure work, but the whole volume of water is so small in any high-pressure apparatus that it heats and flows very rapidly. The water gives off its heat soon, and consequently cools rapidly. The circulation must be limited in length owing to the friction set up in the small pipes. Owing to rapid circulation the pipes can be dipped safely under doorways without checking circulation materially; this cannot be safely done in low-pressure apparatus without special precaution. When an expansion tube is used instead of a safety valve, this tube is full of elastic air when the other pipes are filled with cold water. At starting for the season a hand pump of special construction is applied, and all air is forced out of the pipes, which are then pumped full of water, with the exception of the expansion tube, which is full of air. The screws are then tightened up and fire applied. As the water heats and expands it compresses the elastic air in the expansion tube, and the expanding water rises and half fills the tube, preventing undue pressure on the pipes.

Small-bore hot-water apparatus possesses some advantages. The pipes are easily bent and fitted into small spaces, the temperature of the pipes can be made so high that a foot of 1½in. pipe will give as much heat as a foot of 3in. pipe in low-pressure apparatus, there is a minimum of evaporation, and the amount of water needed is very small. For instance, a high-pressure apparatus of 1,000ft. of 3in. bore pipe contains only 26 gallons, and can be made to yield as much heat as a low-pressure apparatus of 1,000ft. of 3in. pipe containing 300 gallons. This form of apparatus is economical. Small-bore apparatus heats up rapidly and cools down rapidly, and is very easily managed by unskilled attendants. Its disadvantages are that the insurance companies often object to its adoption in buildings containing goods at all liable to take fire, owing to the high temperature the pipes may reach. This high temperature also dries the air (the low-pressure temperature seldom exceeds 200°F.); also, if frost attacks the pipes or the boiler when they are cold and not in use, the water freezes and the pipes burst. This can be prevented by keeping a slow fire on always during frost, but the practice sometimes adopted of using chemicals to prevent freezing is to be condemned as they injure the piping by attacking the iron and also form deposits which choke the small pipes.

Another type of the small-bore hot-water apparatus is made by which a pressure not exceeding 30lbs. per square inch is only permitted. The pipes may be the same as in high-pressure apparatus, or may be of iron steam tubing; radiators are freely used as in low-pressure apparatus, the highest radiators on the upper floor being adapted to act as the expansion tube into which the heated water rises. The amount of piping in the furnace is reduced so that the water shall not be heated beyond a definite point, and thus the pressure also is moderated throughout the system. By this system a higher temperature is attained than in low-pressure apparatus, while the smaller-sized circulation pipes may be used with radiators of ornamental design in the principal rooms; but the perfect safety and simplicity of the open low-pressure apparatus with radiators is not compensated by these advantages.

(To be concluded.)

Coventry Street Improvements.—The Local Government Board has sanctioned the borrowing of £6,068 for street improvements in Coventry.

Dublin Tenement Houses.—The Dublin Corporation has drawn up a set of proposed new by-laws relating to tenement houses, as the old by-laws are out-of-date and inadequate from a sanitary point of view.

Builders' Notes.

The Wallpaper Manufacturers, Limited, is a borrowing rather than a selling company—that is to say, it asks the public to find only £1,314,818 out of a paid-up capital of £4,200,000. The prospectus claims that the ring includes substantially the whole (about 98 per cent.) of the wallpaper manufacturers of the United Kingdom, and boasts that it will be “almost hopeless for anyone to compete with the company,” which has entered into agreements for a fixed period of years with dealers for the distribution of its goods.

The Builders' Clerks' Benevolent Institution.—The annual meeting was held at the offices, 21, New Bridge Street, E.C., on February 27th, Mr. Henry Holloway (president-elect) occupying the chair. The report stated that the income had been £688, and the outgoings £659. The amount paid in pensions was £522 (the largest sum yet disbursed), and in temporary relief £30. The retiring members of the committee—Messrs. E. Brooks, H. T. Desch, H. W. Parker, E. Pitts, A. Stansfeld and C. K. Turpin—were re-elected.

Building in Birmingham.—The building surveyor of Birmingham reports that during the year 1899 there was a slight falling off in the number of houses for which plans were submitted, but in 1898 plans were approved for several estates the buildings on which are still in course of erection, and when allowance is made for this it may still be assumed that there is a progressive increase in the erection of houses. The growth of house building is shown by the fact that in the year ended December 31st, 1896, plans were submitted for 1,852 houses; 1897, 1,836; 1898, 2,308; 1899, 2,145. The increase has been greatest in the Saltley district (in the Washwood Heath neighbourhood), whilst Sparkbrook, Rotton Park, and Winson Green also show large increases.

London County Council.—At the meeting of the Council held on February 27th a long discussion arose on the report of the General Purposes Committee with regard to excess expenditure in respect of the Heath Asylum, Bexley, and the Horton Asylum. In one asylum there was an excess of £75,000, and in the other of £107,000 over the estimates. The original vote for the Horton Asylum was £350,000, which sum had been largely exceeded. Mr. Macdougall said he had never intentionally avoided the Standing Orders. If the committee had made a mistake it was a simple one; they had applied a wrong standing order to their case. Mr. H. P. Harris said that if it was impossible to build the asylum for £350,000, why did the Asylum Committee tell the Council it could be done for that sum? All the architect was instructed to do was to take the £350,000 and apportion it as best he could. To do this he had to leave out items which ought to be included, in order not to exceed the stipulated sum. After further discussion, the portion of the report dealing with the Bexley Asylum was agreed to. Mr. Beachcroft moved an amendment declaring that in the opinion of the Council a grave departure had been made in the case of Horton Asylum from the usual and recognised practice as regards the estimate submitted to the Finance Committee, and that in consequence the Council had virtually been deprived of control over the large excess expenditure, amounting to no less than £107,000. After some further discussion the amendment on a division was lost and the excess amounts were then authorised. The Parks Committee reported that the Archbishop of Canterbury had consented to hand over to the London County Council, to be used as a public open space, a large portion of the grounds attached to Lambeth Palace. The Highways Committee recommended “That the Council do sanction the expenditure on capital account by the Highways Committee of the sum of £250 in respect of a portion of the mains in connection with the electric lighting installation for the Victoria Embankment and Westminster Bridge; estimates in respect of which were submitted to and approved by the Council on July 13th,

1897, and February 15th, 1898.” The Council approved. The entire scheme is estimated to cost £25,800.

Fire Tests with Protective Coverings.

—Publication No. 43 of the British Fire Prevention Committee deals with the firetests with two kinds of protective compositions made by the “Gypsine” Brick Company, Ltd., of London and Paris. Steel joists 7in. deep were employed, one of them being covered by a composition applied as plaster about 1in. thick and the other joist being bedded in a composition about 3in. thick. The following observations were made after the test with regard to the beam of larger section:—There was a longitudinal crack on the soffit of the protecting material for about half the length; there were fine hair cracks on all surfaces of the protecting material; the lower arrises of the protecting material were damaged; the protecting material was very sodden from the applied water, and was very soft and easily impressed; the composition remained attached all round, and the girder was not affected by the test. The following observations were made after the test with regard to the beam of smaller section:—A layer of protecting material to the soffit of the beam about ½in. thick had become detached and had dropped off; the sides of the protecting material showed vertical cracks, and the surface of the material showed fine hair cracks on all faces; there was a longitudinal crack in the protecting material on the top surface; the protecting material was sodden with the applied water, and was soft and easily impressed. By the future arrangements of the British Fire Prevention Committee there will be a number of reports on the various forms of patented or specially made partitions, the following being the names of firms who have either applied for tests or whose partitions are already under investigation:—The London Non-Flammable Wood Co., Ltd. (matchboarded partitions of non-flammable wood); the Gypsine Brick Co. (partitions of gypsine bricks); the Mural and Decorations Syndicate, Ltd. (partition of special lathing); the Fireproof Partition Syndicate, Ltd. (“Cunah-Wright” partition); J. A. King and Co. (Mack's partition); D. Anderson and Co., Ltd. and Broadbent and Co., Ltd., jointly (stud partitions filled in with slag wool).

Engineering Notes.

The Belfast Mechanical and Engineering Association recently held its eighth annual reunion, when Mr. John Erskine, J.P., presided.

Strand Electric Works on Fire.—The large works of the Charing Cross and Strand Electricity Supply Corporation in Maiden Lane were severely damaged by fire on Saturday last; cause unknown.

Wallasey Water Scheme.—A Local Government Board enquiry was held on February 27th into the application of the Wallasey Urban District Council for sanction to borrow £14,000 for water supply works, and £4,500 for the erection of a technical school at New Brighton. It is proposed to construct two boreholes on the site of the existing well at Liscard, one to be carried to the depth of 800ft., and the other to the depth of 600ft. The land for the proposed technical school is situated at the corner of Field Road and Rowson Street, New Brighton, and contains 618 sq. yds., of which 25 sq. yds. are proposed to be added to the highway, leaving the net site 593 sq. yds. The building is two storeys high, with heating apparatus and coal in the basement.

Corrosion in Boilers.—In the course of a lecture on this subject, read before the Institution of Civil Engineers on February 27th, Mr. John Dewrance, M.I.C.E., pointed out that air had been for many years a well recognised cause of corrosion, and that the boilers in which the best means had been adopted to keep out air had been those least affected. It was of paramount importance to return the water from the condenser to the boiler without

allowing it an opportunity of dissolving air. With this aim, Mr. Dewrance suggested that the hot well should be placed between the condenser and the air-pump, making it a separator of water and air. The air-pump would then pump out the air and the feed-pumps pump the water back to the boiler.

Steam Raising.—At the conclusion of a recent lecture, by Captain H. R. Armitage on “Steam Raising Plant,” delivered before the Bradford Textile Society, the following principles for laying down new plant were stated: (1) Chimney: of sufficient area. (2) Boilers: not less than 100lbs. pressure, using full pressure for engines, and reducing for other purposes; the boilers to be without tubes. (3) Flues and setting: bottom flue not less than one-half diameter of boiler; side flues, 12in. wide at the narrowest point. (4) Main flues: gradually enlarging up to chimney bottom, and also enlarged on the outer sides of all curves (as in a river bed), and all bends, either in downtake, uptake, or junction to main flue, to be treated like a flow of water. (5) Economiser: sufficient pipes either for water alone or water and air, if the heated air can be used, to reduce the flue temperature to 350deg. at the chimney bottom. (6) Boiler and pipe covering: leave a stationary layer of air between two layers of covering; this would form an efficient non-conductor, and at the same time flange coverings could be made. This should also be made to fall to a point or two points, where a steam trap should be connected. (7) Method of firing: by mechanical stoker and self-cleaning bars.

Surveying and Sanitary Notes.

Wakefield Sewage Works Opened.—The sewage disposal works which the Wakefield City Council has constructed at Calder Vale were formally opened on March 1st. They have cost £70,500.

Sanitary Inspectors' Association.—The seventeenth annual dinner of this association was held on Saturday at the Holborn Restaurant, Sir H. Gilzean Reid, the president, occupying the chair. The association was formed in 1883 and now has 600 members.

Hackney Vestry: Surveyor's Annual Report.—We have received a copy of the report of Mr. James Lovegrove, A.M.I.C.E., chief surveyor to the Hackney Vestry, for the year ending March 25th, 1899. The total expenditure for labour during this period was £19,066 7s. 10d., while the quantity of materials put on the roads was 18,288½ cubic yards; £5,459 13s. 4d. was spent for road watering purposes. This is Mr. Lovegrove's final annual report, after fifty-three years of office.

Sheffield and the Local Government Board have been playing a game of battledore and shuttlecock for the past seven years over the adoption of a sewerage scheme to replace the present rubble sewers. The Local Government Board has now changed its attitude and is considering the renewed application of the Sheffield Corporation to borrow £68,635. The Corporation are promoting a Bill in the present session of Parliament in which there is a clause to empower them to acquire certain land immediately adjoining the sewage disposal works, containing about 105 acres, for extensions.

Birmingham City Surveyor's Report.—The annual report of Mr. Price (city surveyor of Birmingham) states that during the past year the reconstruction of the sewers has proceeded satisfactorily. The tenders for the work already in hand amount in the aggregate to about £75,000. The most important work is, perhaps, the reconstruction of a length of about 1½ miles of the Rea main intercepting sewer from Montagu Street to the overflow weir on the River Rea at Nechells. The length still to be completed consists mostly of 6ft. circular sewer. Not the least of the

benefits from the above work will be the prevention of flooding, which for years past has periodically taken place in the lower part of Duddeston Mill Road. In the Balsall Heath district extensive works of sewerage and surface water drainage have been completed. A new 3ft. circular culvert in Edward Road now drains a district which previously had been subject to flooding. In connection with the Edgbaston and Harborne scheme, the sewerage of the district lying between Bristol Road and the River Rea is, with the exception of one or two streets, completed, a length of 1½ miles of defective sewers having been taken out and seven miles of new sewers constructed. The expenditure to December 31st, 1899, on that part of the Edgbaston and Harborne sewerage scheme which is being carried out departmentally was £17,175 19s. 5d. Upwards of 30,000,000 gallons of water have been used for sewer flushing during the past twelve months, in addition to the large amount used in the summer months in flushing private drains in courts, yards, and other back premises. The number of loads of mud and dry sweepings removed during the year from the roads was: Mud, 66,205; dry sweepings, 38,499; making a total of 104,704 loads. The heavy fall of snow which took place on December 12th involved the removal of 9,190 loads, and the cost amounted to £1,500 11s. 9d., being an average of about 3s. 3d. per load, inclusive of labour and cartage. About 5,000 tons of granite chippings and crushed gravel were used for gritting granite and wood pavements, and 49,765,245 gallons of water for street watering purposes.

The Birmingham District of the National Association of Master Plumbers, Limited, held their fourth annual dinner last Wednesday evening.

Dunfermline Joiners Dispute Settled.—The operative joiners of Dunfermline have agreed to submit to a reduction of wages from 8½d. to 8d., a compromise from the 1d. reduction at first notified by the masters.

Strike of Aberdeen Joiners.—About 700 operative joiners in Aberdeen struck work last week against a reduction of the standard rate of wages from 8½d. to 8d. per hour. Three masters, employing between forty and fifty men, have already acceded to the demands of the men, but at a meeting of the executive of the Masters' Association it was unanimously resolved to adhere to the decision to enforce the reduction, and also agreed not to meet again for a month.

Trade and Craft.

Light Diffusion.

In nine cases out of ten the aim of the lighting engineer should be, though it often is not, diffusion. Clear, uncovered lights, irrespective of their nature, have the great drawback of injuring the eyesight, and it is now admitted that the ideal lamp is the glow lamp—that is, one having no objectionable incandescent filament or distinct point of light. Prominent experimental electricians in America, like Tesla, have spent a good deal of energy in the attempt to produce a lamp in which the electrical current would expend itself somewhat in the manner of the Geissler tube, rather than the direct heating of a filament; and this surely shows how things are tending. With this same end in view the Spiral Globe Company has put on the market a light-refracting and diffusing envelope for the ordinary electric incandescent lamp in the form of a globe made of a closely-wound spiral of circular glass rod. The statement is made, and substantiated by authority, that, whereas a sixteen candle-power electric lamp (hung vertically) will illuminate the surface directed to it with an effective light of ten candle-power; this lamp, when enclosed in the spiral globe, will give twenty-three candle-power; so that there is an economy of more than fifty per cent., which means a lower electric light bill. In addition, the light is softened so as to be agreeable to the eyes. The Spiral Globe Lamp complete costs 4s. 6d., the lamp itself costing 2s. net, and can be seen and inspected at the company's showrooms at 28, Bush Lane, Cannon Street, E.C.

American Fireproof Construction.

Two matters which have been engaging universal attention during the past decade are—the housing of the poor and fireproof construction. These have a distinct connection with one another, as if huge tenements have to be built containing quite a colony of human beings, they must be planned and constructed so that the risks of fire, and probable resulting loss of life, are reduced to the lowest possible limit. While it is only right that planning should have the first consideration, it needs to be well supplemented by fireproof construction, for the preservation of life ought always to be the great aim and the preservation of property to receive secondary consideration. These two aims must be

judiciously combined. It is of no use if your theatre staircases withstand the flames and yet are so narrow and bent that the people cannot get out of the building; nor is it worth while to have excellently planned exits if their construction is such that they will burn up in no time. Fireproof construction becomes, therefore, an essential factor. The Columbian system, which is extensively used in America, consists of ribbed steel bars of double cruciform section, which are completely embedded in concrete composed of the best Portland cement, sand and furnace slag or cinders. There are three forms of Columbian concrete fireproof floors. First, there is the panelled floor, in which all the joists and main girders are completely encased with concrete and the under side is protected by concrete slabs secured with concealed anchors and providing air space; 2in. and 2½in. ribbed bars hung in stirrups are used to carry 4cwt. to 12cwt. In the second form, the double construction, instead of the joists projecting below the ceiling line, 1in. ribbed bars are laid on the lower flange and a wooden centering is placed below to receive a 2½in. concrete ceiling. Joists are not spaced further apart than 7ft. and this construction is specially adapted for high buildings and heavy floors. In the third form 3½in., 4in. or 5in. ribbed bars are spaced between the main girders, or placed resting on the wall, and the concrete floor is built up around them. This type of floor is suitable for hospitals, asylums, hotels and similar buildings, and 1cwt. to 3cwt. per square foot of surface can be carried with safety. The London offices of the Columbian Fireproofing Company, Ltd., are at 37, King William Street, E.C.

A new Warehouse is in course of erection at Marsh Gate Lane, Stratford, E., for Messrs. T. H. Harris and Sons. Messrs. J. T. Newman and Jacques, 2, Fen Court, E.C., are the architects.

"THEY WILL WANT A LITTLE NURSING," said Sir Redvers Buller of the gallant defenders of Ladysmith, and even after the most careful nursing many poor fellows will be unfit for active service again. Will you help to provide a Home of Rest for some of these? If so, send a shilling—or several shillings if you prefer it—to the B.J. Shilling Fund.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.	WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDER MAY BE OBTAINED.
March	BUILDING—		
9	Aberaman, Wales—House		Manager, Powell Duffryn Co.'s Office, Aberaman, Aberdare.
9	Bronley, Kent—Ambulance House	Hospital Board	J. Ladds, 7, Doughty-street, Meaklenburgh-square, W.C.
9	Rotherham—Generating Station	Corporation	J. Platts, Old Bank-buildings, High-street, Rotherham.
9	West Bromwich—R. offg.	Guardians	T. Rollason, Architect, High-street, West Bromwich.

No date.	Glasgow—District Hospital	£150, £100, £50	J. R. Motion, 33, Cochrane-street, Glasgow.

Property and Land Sales.

To Shop Builders and others.—Romford.—Exceedingly valuable Block of Freehold Building Land in the main station thoroughfare and affording an unrivalled site for a block of first-class shops, for which there is an increasingly great demand in this rapidly-growing suburban town. The property is in the heart of the business portion of the town, adjoins Messrs. Ind Coope's Brewery and the post office, and has a frontage of nearly 18 ft. to South-street, with an excellent depth.

MESSERS. KEMSLEY will SELL the above by AUCTION at the Mart, E.C., on MONDAY, MARCH 27th, in One Lot.

Particulars of **MESSERS. DAWES and SON**, Solicitors, 9, Abing-court, E.C.; and of the AUCTIONEERS, 41, Bishopsgate-street Within, E.C., and at Romford and Woodford Green.

Preliminary advertisement.—**BALHAM**—To Land Companies, Builders, and Others—1½ acres of valuable Freehold Building Land with two first-class family residences thereon, situate in the Balham High-road, about five minutes' walk from the London, Brighton, and South Coast Railway, having an important frontage of 200 ft. to the main road, with a depth of nearly 40 ft. The detached residences lie well back from the road, are approached by carriage drives, have ample accommodation for large families, with stabling and ornamental gardens, &c. Let at ground-rents together of £70 per annum, for terms expiring in about three years, thus affording ample opportunity for judiciously laying out the property. It is ripe for immediate development into first-class shops with superior residential flats above, also forms a valuable adjunct to adjoining lands with which it could be laid out to very great profit.—Messrs.

FAREBROTHER, ELLIS, EGERTON, BREACH, GALSORTHY and CO., will SELL by AUCTION, at the Mart, Tokenhouse-yard, the above important PROPERTY early in the Spring.

Particulars may be obtained of Messrs. Farebrother, Ellis & Co., 29, Fleet-street, Temple bar, and 18, Old Broad-street, E.C.

Detailed List of Books post free on application.

B. T. BATS-ORD,

94, HIGH HOLBORN, LONDON.

R.I.B.A. EXAMS. PREPARATION, personally or by correspondence, in three, six, nine, or twelve months' courses. Architectural Lending Library. Special three months' finishing courses.—For full particulars apply to Messrs. HOWGATE and BOND, Associates R.I.B.A., 115, Gower-street, W.C. (close to the British Museum).

MODELS.

For Exhibitions or Law Cases. Illustrations sent of Work Executed. JOHN B. THORP, 98, Gray's Inn-road, W.C.

WOODWORK.—A thoroughly equipped Workshop, having railway siding and water frontage, first-class British and American tools, capable manager and workmen with many years' experience, OPEN TO EXECUTE ORDERS for any class of woodwork, in the rough or finished, either to model, drawing, or specification, large stock of thoroughly seasoned wood always on hand.—Apply, DALMEIN, care of BUILDERS' JOURNAL.

NOW READY. Price Four Shillings.

Laxton's Builders' Price Book
FOR 1900.

"The acknowledged standard work of reference."

CONTAINING ABOVE 72,000 PRICES,

together with many useful and important Memoranda and Tables, and Prices and Descriptions of New Materials and Inventions suited to the Builder, Contractor and Engineer, and all Trades connected therewith.

The whole carefully corrected and revised according to the present Prices of Materials and Labour. Contains:

THE LONDON BUILDING ACT, 1894;

also the RULES OF PROCEDURE IN CASES to be brought before the TRIBUNAL OF APPEAL appointed under the LONDON BUILDING ACT, 1894; By-laws of the London County Council and the City of London; also Regulations by the Council applying to Theatres and other Places of Public Amusement; List of Aldermen and Councillors of the London County Council; also the District Surveyors, with their respective districts.

Notes of Cases & Decisions in the Superior Courts.

KELLY'S DIRECTORIES, LTD.,

182, 183, & 184, HIGH HOLBORN.

SIMPKIN, MARSHALL, HAMILTON, KENT & CO. Limited, Stationers' Hall Court, E.C.

AND MAY BE ORDERED OF ALL BOOKSELLERS.

APPOINTMENTS VACANT.

The charge for Advertisements under this heading is 1s. 6d. per insertion not exceeding four lines, and 6d. per line afterwards, prepaid. Three insertions may be had for the price of two.

WANTED, ESTIMATING CLERK; must be able to take off and prepare bills of quantities, and have had experience of provincial practice. Salary £2 5s.—Apply, "Architect," care of Messrs. Willans and Robinson, Rugby.

APPOINTMENTS WANTED.

The charge for Advertisements under this heading is 1s. 6d. per insertion not exceeding four lines, and 6d. per line afterwards, prepaid. Three insertions may be had for the price of two.

YOUNG ARCHITECT, A.R.I.B.A., ASSISTS in the PREPARATION OF DRAWINGS, TRACINGS, &c., at his own Office. G. SCOREE, 28, Newman-street, W.

SANITARY INSPECTORS' EXAMINATIONS.—An Associate of the Sanitary Institute thoroughly PREPARES CANDIDATES for the above Exams. by correspondence; no books are required.—For particulars and testimonials apply, "Certified Coach," "Malabar," New Eltham, S.E.

IMPROVER.—Architect's Clerk, finishing articles on South Coast, March 24th, desires immediate ENGAGEMENT as IMPROVER in London architect's office.—H. WILSON, Homestead, Clifford-road, Bexhill-on-Sea.

SAWYER WANTS JOB; can work band or circular, used to sharpening own saws if required.—Address, "A. T.," 53, Caistor-road, Balham, S.W.

QUANTITIES.

H. B. JOHN, P.A.S.I.

TUDOR VILLA, TUNBRIDGE WELLS. 1

QUANTITY SURVEYORS and ARCHITECTS.—ASSISTANCE RENDERED in Taking-off, &c., by the hour, or on commission. References given.—"H. R. A.," 22, Ellison-road, Streatham, S.W.

GENERAL FOREMAN seeks RE-ENGAGEMENT. Five years with late employer. London and provincial experience. Excellent references and testimonials. Joiner, age 28.—Address, M. GRASSMERE, Selly Park, Birmingham.

WEST RIDING OF YORKSHIRE.—QUANTITIES PREPARED, specifications written, plans traced, &c., by Architects' Assistant in spare time. Charges moderate, prompt attention.—Apply, Box 1,320, BUILDERS' JOURNAL.

QUANTITIES PREPARED, SPECIFICATIONS WRITTEN, &c., by Experienced London Surveyor; full responsibility taken; terms by mutual arrangement.—Box 1,212, BUILDERS' JOURNAL Office.

ABLE ASSISTANCE.

WORKING and DETAIL DRAWINGS, DESIGNS, PERSPECTIVES, TRACINGS, QUANTITIES and SPECIFICATIONS, DIFFICULTIES of PRACTICE advised upon. F. BRENT, 7, Stanley Villas, Lyndhurst Road, Wood Green, N.

ARCHITECT wishes to RECOMMEND to London Office a good, all-round JUNIOR ASSISTANT, who has been with him five and a half years, and given every satisfaction; moderate salary.—Box, No. 1,399, Office of BUILDERS' JOURNAL.

QUANTITY SURVEYING. — LESSONS GIVEN by experienced London Surveyor personally or by correspondence.—Apply "Surveyor," Second Floor, 113, Leadenhall street, E.C.

ARCHITECT and SURVEYOR'S JUNIOR ASSISTANT (2) desires ENGAGEMENT; three and a half years' experience.—Apply, "F. C.," 125, Bevan-street, Lowestoft.

GENERAL or SHOP FOREMAN seeks ENGAGEMENT. First class reference. Good manager of men; aged 33. Careful with extras and omissions.—"D. R.," 16, High-street, Harlesden, N.W.

TELEGRAMS: LONDON TELEPHONE No. 1011 Holborn
Dividore London." **DRAWING & TRACING OFFICE.**

Important to Architects.

It often happens that in addition to preparing plans for the erection of a public building or private house, an architect is called upon to carry out a scheme of interior decoration and furnishing.

In order that this may be done satisfactorily it is necessary to take into consideration the style to be adopted in relation to the architecture of the building treated, and also the schemes of colour and materials to be used in the decoration of surfaces.

Formerly the difficulty has been to find an authoritative publication which would be a reliable guide to those engaged in this branch of the profession, and one which would introduce new ideas for interior decoration in addition to keeping a record of all the novelties introduced by the manufacturers of furniture and fittings.

The proprietors of the "Builders' Journal" have therefore pleasure in directing the attention of the profession to their new monthly publication THE FURNISHER, which deals exhaustively with all branches of the furnishing trades. This publication is divided into sections dealing with "Furniture and Upholstery," "Decoration," "Metal Work," "Lighting and Heating," "Pottery, China and Glass," and "Silver and Electroplate." Each issue contains original designs and suggestions by well-known modern designers, and plates are given from time to time, with examples of the best work of some of the older schools. The journal is printed on superior paper, and illustrated in first-class style, and is worthy of the attention of all who have in any way to deal with the furnishing and decorating of public buildings or private dwellings.

PUBLISHED ON THE 15th OF EACH MONTH.

Price 6d. nett.

An Architectural Causerie.

Public Buildings and Heraldic Decorations.

PROBABLY one of the most marked architectural effects of the capitals of England, France, Germany, and the United States, is afforded by the lavish way in which hotels and restaurants are now built. These establishments may well be described as palatial, although, no doubt, the true artist will often have to deplore the way in which the architect's mind has run riot, both as regards fantastic designing and over-elaboration in decoration. Taken as a whole, however, great progress has been made of late, for, apart from the question of mere size, the accommodation in the modern hotel and restaurant is certainly more convenient than it was of old. The tendency, which at one time undoubtedly existed, to build hotels somewhat on barrack lines has given way to more rational ideas, and it is recognised that even a big place can be made handsome and given the comforts which one might expect in a well-regulated home. In many instances establishments, or special apartments, have been fitted up and decorated with a fair approach to exactitude to some historic period. It is noticeable that heraldry plays a great part in many of these schemes of decoration. We find armorial bearings and badges sculptured in stone, carved in wood, wrought in iron, moulded in terra-cotta or plaster; they are shown in the illuminated windows, and introduced into the colour schemes of mural paintings. Good examples can be found in London, and even in New York, but the latest and one of the most thorough object lessons is afforded by that superb new restaurant in Berlin, the Kaiser-Keller, just off Friedrichstrasse. Externally rather more striking than dignified, the Kaiser-Keller is admirably planned for its purpose, and contains a number of big halls, decorated in a strange variety of styles, but each apartment perfect in itself. Both painter and carver frequently make use of heraldic symbols. On the first floor is one of the most important of the salons, known as the Hohenzollernsaal. It is quaint, being long and vaulted, a faithful representation of an old German castle hall. The chief mural ornamentation here consists of the genealogical tree of Hohenzollern line. The tree ascends from a golden castle, flanked by two knights in black armour. The branches reach to the ceiling, and spread out 45ft. The branches are numerous, adorned with names, portraits, and the proper armorial insignia. It must have been a gigantic undertaking, and though far too gorgeous for an ordinary hall, looks well enough in the vaulted chamber. Fronting this Royal and Imperial tree, the civic arms of the chief towns of the Province of Brandenburg are tastefully arranged amidst conventional designs. This is, of course, an

extreme case. Such a surfeit of heraldry would be inappropriate anywhere else than in a dining hall designed on historic lines, admitting of the lavish display of contrasting primary colours and the two precious metals. It is to be noted that the treatment of the symbols must necessarily vary with the architectural style. With Gothic surrounding, or in baronial halls, free play may be given to the artist's fancy as regards the outline of shields and outward ornamentations, and the drawing of animals, &c. When the building is more or less strictly classic,

from all others by means of a series of vertical or horizontal fire-resisting screens or partitions. Much the same sort of thing happened with regard to drainage some years ago, when over-trapping was rampant, the bottling up of the sewer gas within the drains being aimed at; whereas now it is recognised that trapping, though essential within proper limits, yet has its limits of efficiency, and that proper ventilation has also to be secured. So, in the opinion of fire-

EDWARD R. TAYLOR, HEAD MASTER OF THE BIRMINGHAM MUNICIPAL SCHOOL OF ART.

heraldry must be severely subordinated, the shields must be as plain as possible, and all drawing quite formal, and even then such shields can only be used for interior decoration.

G. C. R.

Fireproof Construction: the Fireman's Standpoint.

THERE are two ways of looking at most things, and this seems to be the case with fireproof—or, more correctly speaking, fire-resisting or slow-burning—construction. When first the subject was brought into public notice, none save the most drastic methods were thought to be of any use—the absolute cutting off of the burning portion of a building or its contents

men of experience, it seems to be with a burning building. Separation into fire-tight compartments, corresponding to the water-tight compartments of a ship, is well if complete and in small sections, but needs combining with some means for free vent of the flames and the gases evolved in a direction in which they will do no harm. Evolved they are, and escape they will in some direction or other, and if prevented from doing so vertically they will be sure to spread laterally. The position of windows is, therefore, of great importance, that the escaping flames may do no damage to neighbouring property, while the firemen may be provided with means of entry, or at least with the opportunity of pouring water through them upon the burning mass within. In this connection the provision of a roof of fire-resisting material seems, from the fireman's point of

view, to be a mistake, confining the flames, and forcing them out laterally when they might have a free outlet upwards without any material risk of damage to neighbouring property, for with party walls properly carried through the roof it is almost impossible for burning timbers to fall or be thrown from one building to another. Another advantage of a roof which burns through and falls in is that it allows water to be poured downwards through the gap; but the chief one is that the flames ascend without seeking fresh fuel and lateral outlet. With regard to staircases, forming as they always do natural tunnels for communicating fire from floor to floor, by all means cut them off from the floors which they serve with hardwood doors, for which, as also for the floors themselves, teak is the best material. Wood is in fact liked much better by the fireman than is generally understood—he always prefers it to metal, and for stairs at least he places it in a higher position than stone or concrete. The reason is plain; he can at once see by inspection whether it is safe to trust himself to timber or not, whereas other materials are dangerously treacherous under extreme heat; and it takes a great deal of burning to do more than char the surface of a solid beam, or stair, or door of such a wood as teak. There are men who go so far as to say that few so-called fireproof floors will confine a fire so well as one of hardwood boards, tongued with hardwood tongues so that the flames cannot penetrate the joints—while a built-up teak staircase is permitted for warehouses under the stringent London regulations. As for a floor or staircase of solid balk timber, it is almost indestructible by fire under any save most abnormal conditions.

G. A. T. M.

Cement Tests.

THE recent flotation of a limited company to take over a big Portland cement factory discloses the fact that one well-known firm of contractors requires at least 50,000 tons of this material per annum. Probably this enormous figure does not excite the attention it would have done fifty years ago; but this alone is proof of the important position held by Portland cement in the field of modern construction. In considering the multitudinous building purposes for which it is employed, the necessity for more clearly studying and understanding this material becomes increasingly evident. The paper read by Mr. W. G. Day before the College of Masons last month, which appears in our columns this week, reveals many little points in the origin, composition, and manufacture of cement that we think will be useful to our readers. The summary on testing is a useful addition to the paper, for the mistake most commonly made by architects and engineers is in specifying impossibilities, and very frequently extravagant demands are made "in order to be on the safe side," which no maker can possibly fulfil. There are various tests for fineness, specific gravity, chemical analysis, tensility and adhesion, heating and expansion, issued by the Cement Users' Testing Association, and they also give tests for three qualities, the first for engineering works requiring great strength, the second for engineering works not exposed to great strain and for first-class architectural works, and the third for general purposes. A study of these tests would often make the specification a much more useful document than it is.

On Reflection.

Picketing. THE law relating to picketing is now clear of ambiguity.

This has been brought about by the case of *Lyons v. Wilkins*. Section 7 of the Conspiracy and Protection of Property Act, 1875, says that you must not, under penalty, watch or beset a house or other place for the purpose of getting anyone to abstain from doing what he has a legal right to do; but there is the limitation that "attending at or near a house or place where a person resides, or works, or carries on business, or happens to be, or the approach to such house or place, in order merely to obtain or communicate information, shall not be deemed a watching or besetting within the meaning of this section." It used to be thought that this proviso allowed "peaceful picketing," that is to say, it allowed a workman who had had a difference with his employer to quietly argue with his fellow-workmen and try to get them to throw up their work. It was, of course, always understood that violence and intimidation were illegal. In the case of *Lyons v. Wilkins* the plaintiff's premises were picketed in the usual manner, so they applied for and obtained an injunction to restrain the defendant from watching and besetting, except for the purpose of obtaining or communicating information. They afterwards obtained a perpetual injunction, and, as the appeal to the House of Lords has been abandoned, the holding of the Court of Appeal on December 20th, 1898, is the law. By this holding pickets must confine themselves to their legitimate business, and not argue—simply obtain or communicate information. The Employers' Parliamentary Council (whose duty it is to take action in respect of any Parliamentary Bills or the action of Imperial or local authorities affecting trade) thinks that the days of effectual picketing are thus numbered. But we are of opinion that the difficulty of determining whether a man has come to argue and entice or simply to "obtain or communicate information" will still give rise to much controversy and litigation.

A Case for Reform.

THERE are a number of good old institutions in this country that require shaking up and resetting, and prominent amongst them is that laborious, ill-systematized and inefficient creation, the Patent Office. The wretched state of our patent laws is notorious, and it is largely due to this that so many worthless patents yearly tax the brains of persons who fancy they have discovered the philosopher's stone; but fancy soon turns to disappointing fact—after patenting. For those who do not know, it may be well to state that it is possible to take out a patent in this country for something which has already been patented, all that is asked being that you should conform in your application and specification with some stereotyped requirements and pay the fees. The method of comparing us with other countries (to our detriment, of course) is a popular one at the present time, and through it a deal of good has resulted; and it may, therefore, be well to enquire how patent matters are managed in the United States, a land full of innovations, excellent and otherwise. In order to ensure novelty, a body of experts is connected with the American Patent Office, so that when the inventor's application is sealed he knows that his is a new invention, and that he has procured real protection for it. To illustrate how this protection does not exist here, we may mention an instance in which an old and well-known window fastener was sent up some time ago and was patented again, though no

change whatever had been made to it! The result of all this is that when an inventor finds his idea stolen (and unscrupulous infringers are not lacking) it is futile for him to wave aloft his sealed patent, and he either has to let things go on or drag the matter into the Courts, where he often becomes ruined, or finds that his costs exceed what he would have lost if he had not sought the law for protection at all. Moreover, the British system does not foster invention, one reason being (apart from the insecurity of patenting) that its fees are too high. Adding up all the fees, every invention costs the inventor £99 for fourteen years, as he is required to pay an increasing yearly fee during the term of his patent. In America he can obtain real protection for seventeen years for £7. This fact speaks for itself. See what a change took place when the "Patents, Designs, and Trade Marks Act, 1883," came into force. In 1883 the total number of applications for patents was 5,993; the next year it went up to 17,110. And no doubt a similar increase would take place if fees were again reduced, while, if a proper examining board were instituted, ignorant inventors would be saved throwing away their money on useless or antiquated inventions, and the clerical staffs would be saved a good deal of trouble. Less than 7 per cent. of all the patents granted and sealed are on an average kept in force to the end of the thirteenth year by the payment of renewal fees. The object of these fees is said to be twofold; to reduce the number of useless inventions, and to increase the revenue. Well, useless inventions die very soon without any help, and the fault lies in allowing them to be taken out; while figures prove that if renewal fees were abolished (they produced £122,987 in 1898) and a single low fee introduced, the Patent Office would still have a balance on the right side. An excellent little pamphlet by Mr. James Keith, C.E., on "Our Patent Laws" (originally published in 1890) sets forth these facts, and mentions that a Departmental Committee has been appointed on the subject of patent facilities; whether this will do good or not time will show. Let us hope it will, for our present system of patenting is bad enough in all conscience, and needs a lot of remedying to make it what it ought to be—a real means of protection within the reach of every inventor.

Freestone and Brick.

IF there is one feature of modern building which is overdone, it is the wholesale mixture of freestone and red brick; we see it at every corner, and the house often looks more like a doll's creation than the work of an architect. Bands of the freestone are added indiscriminately, it surrounds the window openings, forms the corners, and is inserted in great blocks at various heights. The result of all this is that many architects are becoming thoroughly tired of this ubiquitous mixture—and rightly so. Why it should be thought indispensable to employ freestone in this manner can surely only find an answer in the corruption of the modern architect. There seems to be very little attempt at originality, no noble ideal; nothing but a commonplace commercialism pervading the whole. Freestone requires careful employment with brick, for it is most apt to produce a spotty, unstable effect, which is, of course, highly undesirable. The number of houses built of red brick alone is now proportionately small, for if freestone is not used it is pretty sure that some terra-cotta will be. Yet a well-built house of red bricks throughout looks exceedingly well, especially if red tiles are used for the roof, and, this being so, it seems a pity that when there is a possibility of attaining to something like an artistic result it should be so harshly marred by this promiscuous use of freestone.

[PANEL FOR BIRMINGHAM MUNICIPAL SCHOOL OF ART EXTENSION. BY BENJAMIN CRESWICK.]

BIRMINGHAM MUNICIPAL SCHOOL OF ART.

By E. PRESTON HYTCH.

IN view of the extension of local government in Great Britain, and as an encouragement to the advocates of municipal art teaching, it may be interesting to trace the development which has followed the transfer to the Corporation of the classes conducted until 1885 by the Birmingham Society of Arts and School of Art. As early as 1821 several prominent townsmen endeavoured to provide for art instruction in a manner adequate to the requirements of Birmingham; and from that day to this a succession of earnest and capable men have laboured self-sacrificingly in this cause. Despite the importance to the trades of the town of a knowledge of drawing, modelling and design, the assistance of a body of subscribers, and, in later years, the pecuniary and other encouragement willingly afforded by the Department of Science and Art, it was not until 1876 that the future of the work began to appear hopeful. In that year the late Miss Louisa Anne Ryland, a benefactress to whom Birmingham is indebted in many ways, presented to the School of Art the sum of £10,000 to be applied partly in augmentation of the head masters salary and partly in the provision of free admissions and scholarships. This gift was followed in 1877 by the appointment as head master of Mr. Edward R. Taylor, who had been head master of the Lincoln School of Art since its establishment in 1863 and whose brilliant career there is still remembered.

There are many ex-students who gratefully recall the advantages derived from the School of Art when it was largely supported by voluntary subscriptions; and who owe to the school much of their success in after-life, especially in industrial pursuits. Previously to the transfer, the school was already a force in Birmingham. The list of devoted chairmen includes the name of James Prince Lee, at one time head master of King Edward's School, Birmingham, and afterwards Bishop of Manchester; the late Mr. William C. T. Dobson, R.A., and the late Mr. George Wallis, F.S.A., keeper of the art collections at the South Kensington Museum, had served in the head mastership; and the school had numbered amongst its students, with many others whose names are less familiar, Mrs. Allingham, Mr. W. A. Breakspeare, Mr. Walter Langley, R.I., Mr. George T. Morgan, engraver to the U.S. Mint, and Mr. W. J. Wainwright, A.R.W.S. The main strength of the school then, as now, lay in its popularity and its usefulness amongst the large body of local craftsmen. But those who have read the reports of the Committee, particularly during the chairmanship of the late Mr. John Henry Chamberlain, F.R.I.B.A., and those who were then students—and amongst the ex-students are many who are now practicing architects—will recollect how pressing was the need of adequate classrooms and examples.

In 1879, Mr. John Thackray Bunce, a member of the Committee who had long been impressed with that need, published in the "Birmingham Daily Post" an article setting forth the great disadvantages under which the school laboured from the want of suitable accommodation. It was fitting that the first res-

ponse should come from a local manufacturer. Mr. (now Sir) Richard Tangye stated, in his letter dated November 8th, 1881, and addressed to Mr. Bunce: "I was much impressed by what you wrote, and determined to do my best towards supplying the deficiency." At the same time Mr. Tangye enclosed a letter to the then mayor (Alderman Richard Chamberlain) offering on behalf of himself and his brother, Mr. George Tangye, £10,000 (afterwards increased to £10,937) towards the provision of new buildings on condition: "first, that the property shall belong to the town, and secondly, that the town council shall assume the maintenance and control of the school as soon as it is practicable for it to do so." In addition to this generous offer, Mr. W. B. Cregoe Colmore undertook to present to the Corporation a site, valued at £14,000, and the late Miss Louisa Anne Ryland to give £10,000 towards the building. These offers the Town Council accepted. Accordingly there was

included in the Birmingham Corporation (Consolidation) Act, 1883, a clause empowering the Council (a) to meet out of the Free Libraries Rate any deficiency in the fees, grants, and other receipts of the school, and (b) to increase that rate, if required, beyond the usual limit of 1d. in the £1. The Central School of Art had grown so much that in 1890 the Council authorised the lease for ninety-nine years, at an annual rental of £266 15s., of a piece of land for the extension of the building. This extension was completed in September, 1893, at a cost of £17,798. The Department of Science and Art granted £1,038 on the fittings and casts for the original building, and Mr. W. B. Cregoe Colmore £1,000 towards the cost of the addition. The total capital value of the school as it stands to-day is £56,844, and the net capital cost to the Corporation is £19,869. While not making any further condition as to the above-mentioned gift from himself and his brother, Mr. Richard Tangye expressed, in another letter to the Mayor, "a very strong feeling as to the architect who should be employed to carry out the work," and added that "Mr. John Henry Chamberlain possesses in an eminent degree all the requisite qualifications." The designs and plans of the original municipal school were prepared, almost to completion, by Mr. John Henry Chamberlain, and the tenders for the building, issued under his direction, were received on the day of his lamented death—the 22nd of October, 1883. On the death of Mr. Chamberlain the Committee appointed his partner, Mr. William Martin, as architect to the building, with instructions to carry out Mr. Chamberlain's designs. The firm of Messrs. Martin and

Chamberlain also supervised the extension of the school.

This central school, with its branches held in the evenings in Board schools in different parts of the city, was the first municipal school of art in the United Kingdom. All the work done in the classes is "technical instruction" as defined in the Technical Instruction Acts of later years, whose provisions with regard to art were anticipated in the above-named local act of 1883. The new school was opened in September, 1885. It is managed by a committee, which also controls the Museum and Art Gallery and Aston Hall, the latter a fine example of Elizabethan architecture, formerly the residence of the Holte family and now used as a supplementary museum. The original members of this Museum and School of Art Committee included, as representatives of the Town Council, Aldermen Richard Chamberlain and William Kenrick, and Councillors John B. Hardman, Alfred N. Hopkins, G. J. Johnson, R. F. Martineau, Maurice Pollack, and Charles Wallis; and, as representatives for life of the former Society of Arts and School of Art, Messrs. John Bragg,

John Thackray Bunce, Charles James Hart, Councillor Alfred Clarkson Osler, Jonathan Pratt, Edwin Smith, James Henry Stone and Edmund Tonks, B.C.L.—a list which includes names distinguished not only in municipal administration, but also for the application of art to important local industries. Alderman the Right Hon. William Kenrick, P.C., son of Mr. Archibald Kenrick, one of the founders of the Society of Arts in 1821, has been chairman of the Museum and School of Art Committee since its establishment; Mr. Bunce was chairman of the Building Sub-Committee which superintended the erection of the school and chairman of the Management Sub-Committee from its formation in 1885 until his death in 1899. The continuity of policy and method thus ensured has been of the greatest possible value. There are other sub-committees; namely, the Finance and the Visiting and Examinations Sub-Committees. The position of a member of the Committee is no sinecure; the members regularly visit all the schools under their control. One of the first duties undertaken by the Committee was the revision of the students' fees. In this revision they adopted the principle of maintaining a fairly high scale in those classes attended by students who could afford to pay adequate fees for instruction, and of making a substantial reduction in other classes, particularly in the branch schools. The important object of educating a purchasing class, whilst facilitating as much as possible the art instruction of those engaged in the trades of the town, was thus fulfilled. As a testimony to the esteem in which Mr. Kenrick is held in connection with his assistance to the school, a portrait, executed and presented by Mr. E. S. Harper, was unveiled last Saturday evening on the occasion of the distribution of prizes at the Central School.

The organisation of art teaching in Birmingham has attracted the attention of many specialists, not only in Great Britain and the Colonies, but in America, France, Germany, and Belgium. What most impresses these visitors to the school is the completeness of the educational ladder as regards art, and the valuable and cordial co-operation of other educational and industrial authorities. The work of the School of Art begins with the lowest standard in the boys' departments of Board schools within the city, for the Committee have entered into an arrangement with the Birmingham School Board for the general supervision, by officers of the school, of the teaching of drawing in all the boys' departments of Board schools. The art instruction given in the Board schools is thus

PANEL. BY HENRY A. PAYNE.

pursued on the same lines as in the central and branch schools of art, and one of the greatest advantages of this system is that a boy, after leaving a Board school, and on joining one of the schools of art, is able to continue his art studies just from the point which he reached at the Board school. In pursuance

MODELLED PANEL: "THE SEASONS." BY FRED. MASON.

of this scheme the city has been divided into three divisions; in charge of each division is an inspecting teacher, whose duty it is, at least twice a month, to visit each school in his division. The inspecting teachers are required to discharge the following duties:—(1) The frequent and regular inspection of the drawing taught in each of the boys' schools; (2) the arrangement with the head master of each Board school of the course of instruction in drawing and the proper classification of scholars for that subject; (3) the giving of model lessons so often and of such a character as to instruct the class-master in his methods of teaching; (4) the examination of the drawing done, and the transmission to the head master of the Board school, when required, of written criticisms and suggestions thereon; and (5) the supply of reports to the school management committee of the Board.

There are fifteen branch schools of art—twelve of them held in Board schools in different parts of the city. One is conducted in the Vittoria Street building, which was acquired by the Council, adapted and equipped at a cost of £3,500, and opened in September, 1890. Another is held in the special building in Mosley Road (corner of Lime Grove), built and equipped at a cost of £10,000, and opened on November 18th, 1899. Mr. W. H. Bidlake, M.A., A.R.I.B.A., the special lecturer on architectural history and architectural design at the Central School, was architect of this new branch school. The course of instruction at the branch schools includes elementary drawing, drawing from models, elementary design, light and shade from nature, casts and objects, sepia drawing, geometry, perspective, elementary modelling, elementary modelled design, &c. Building construction, also, is taught at four of the branch schools. At the Moseley Road branch school afternoon and evening classes are held, and the fees are the same as at the Central School. The fee for attendance at any other branch school on five evenings a week throughout the school year of thirty-two weeks is five shillings; and, in addition, a drawing board is provided free for each student. There is thus a branch school within easy reach of every part of the city, and the fee for attendance is so low as practically to exclude none. The Vittoria Street branch school is specially intended for those engaged in the jewellery and kindred trades, such as brass-workers, chain makers, chasers, clerks, damasceners, designers, die-sinkers, enamellers, engravers, jewellers' case makers, lapidaries, makers of electro-plate, mounters, repoussé workers, setters, silver-smiths, stampers, tool-makers, travellers, ware-housemen, and any others connected with the metal trades; and other students are admitted so far as space allows. The classes at this branch school are taught by men who are at once qualified art teachers and practical jewellers, and are attended by about 460 students. About 265 female pupil and candidate pupil teachers, under the Birmingham School Board, receive instruction in drawing at the Ratcliff Place branch school; 250 pupil and candidate pupil teachers in the denominational schools attend other branch schools. The main object of the branch schools is to receive students immediately on leaving the day schools, whilst their fingers are still supple, and before they have lost any proficiency in drawing which they may have already obtained, to give to them a thorough grounding in drawing, modelling, design, and the principles of ornament, and thus to equip them for more advanced instruction, either at the Central School of Art or elsewhere, and for the better discharge of their daily work. Every student's course of study is arranged separately, and to bear on his or her occupation. The average student finds in the branch schools a course of study sufficient to occupy him on two or three evenings a week for three or four years. The casts and other examples are carefully selected; the teaching staff is able, experienced, and enthusiastic, and includes some of the most distinguished ex-students of the Central School.

(To be concluded.)

"BUILDERS' JOURNAL" SHILLING FUND.

THE scheme for providing homes of rest for discharged soldiers as a gift from the combined building trades of the country is everywhere being warmly taken up, as will be seen by the long lists of contributions in kind and money which have appeared in our columns. A remarkable testimony to the enthusiasm the proposal has aroused was given last Monday week at Leicester, when a concert was arranged by the local branch of the Master Builders' Association in aid of the fund. The committee decided to organise a procession as an additional attraction, and this was well attended. The trade unions in the town connected with the building industry readily sent contingents, the bricklayers and federated labourers bringing their banners. A contingent of police led the way, followed by about a score of firemen as torch-bearers. A couple of trowel-bearers were at the rear of the firemen, preceding the band of the local Volunteer Battalion. Close behind were the members of the Bricklayers' Union, with their banner, headed by their president and secretary. The plasterers, painters, wood-cutting machinists, employers in the building trade, general labourers, stonemasons, plumbers, carpenters and joiners, and federated labourers followed in the order mentioned, the latter association carrying its banner. A body of smiths and fitters brought up the rear. The concert was a huge success in every way. Spacious as the Floral Hall is its accommodation was severely taxed by the vast audience, which packed floor and gallery alike. The concert was followed by a speech from the Mayor, and a vote of thanks was carried to him and the Mayoress on the proposition of Sir Israel Hart, seconded by Sir John Rolliston.

Our offer of a copy of the current issue of "Specification," the invaluable reference book for all connected with the building trades, sold at 5s. nett, is still open to anyone who collects twenty shillings for the fund we have opened for those who do not feel in a position to send a large cheque to the General Executive.

The following subscriptions have been received since the publication of our last list:—

The executive of the Building Trades' Gift inform us that in response to the unanimous request of the stewards, Messrs. George Trollope and Sons have kindly consented to act as the builders of the Homes of Rest for Discharged Soldiers, to be erected at Bisley. The donors can hence now rest assured that the workmanship on the Homes in question will do every credit to trades concerned. The executive also wish to announce that, thanks to the generosity of the Right Hon. Lord Pirbright, P.C., the site for the Homes has been extended by an additional two acres, with the result that the property is now well rounded off, and the buildings can be grouped in a very satisfactory manner. The result of the first six weeks' work on this scheme as ending March 1st, has been a collection of gifts in kind to the value of £12,500 (taken at trade prices), and a monetary collection of over £1,000, making £13,500 in all. To complete the scheme, another £5,000 in cash is urgently required, as well as gifts in kind to the value of £6,000. Considerable quantities of timber, joinery, lime, cement, and facing bricks are still required, but particularly timber, the firms connected with the timber trade being conspicuous by their absence on the lists of donors. Regarding such materials as stock bricks, glass roofing materials, paints, &c., in respect to which the entire quantity required has been presented by individual donors. The executive wish to call the attention of the special trades concerned to the fact that the generosity of single representatives should not prevent the remaining firms in that trade from contributing cheques to meet the cost of labour in putting these materials together. The brickmakers in particular are reminded that although Messrs. Eastwood and Co. have splendidly given the material (750,000 bricks), there is no reason why the other brickmakers should not help in paying for the bricklaying.

The following additional contributions in money and kind have been received at the offices of the Executive of the Gift:

CONTRIBUTIONS IN KIND.	
Messrs. J. Tylor and Sons.—Sanitary Equipment for the Recreation House.	
The Crittal Manufacturing Co. (Baintree).—The entire Metal Casements for a pair of Homes.	
Messrs. Walter Macfarlane and Co. (Glasgow).—Rain-water Pipes, Gutters, &c., for one Home.	
Messrs. David Rowell and Co.—750ft. of Iron Railings.	
Messrs. Rowson, Drew and Co.—Two 54in. Double Ranges.	
Messrs. W. N. Froy and Sons.—Twelve Chimney-pieces.	
Messrs. Jacobs Brothers and Co.—50 Tons Portland Cement.

ARTIFICIAL HEATING.*

By W. R. MAGUIRE, J.P., A.I.C.E.I.,
Vice-President Institute of Heating and Vent-
ilating Engineers, London.

(Concluded from page xxxv. of the supplement
to last week's issue.)

Steam Heating.

ARTIFICIAL heating by steam now claims our attention, as it is coming more into use every year. It is not very safe to introduce steam heating under high pressures, except, perhaps, in factories or places where very high temperatures are needed in manufactures and processes where suitably strong pipes and fittings are used; but in connection with radiators such as are now used in dwellings, 13lbs. of steam should be the maximum pressure allowed—3lbs. will be much more suitable and safe. It has already been stated that steam at and under atmospheric pressure is now being used in America, and this system is also being adopted in England. We may allow high-pressure steam heating to pass and turn our attention to low-pressure steam heating at from 2lbs. to 10lbs. per square inch.

In New York there are some buildings thirty-four storeys high, and very many from fifteen to twenty storeys high, built in flats and heated by one installation. An ordinary hot-water system would not be suitable because the pressure on the boiler in the basement from a column of water thirty-four storeys high would be something like 150lbs. per square inch, and in the lower flats the water might rise to a temperature which would blow off in steam on the upper flats. Therefore, in high buildings hot-water apparatus is generally unsuitable for artificial heating, and in buildings of wide extent hot water travels too slowly to afford satisfactory results in portions far distant from the boiler. In such cases steam has no rival for artificial heating. It is not, however, very generally understood in this country. There are at least five different systems of ordinary steam heating under pressure. The first consists of a steam boiler, usually placed in a basement cellar, having a steam main pipe leading from the top, with a steady rise to the furthest point so that condensed steam water may flow back through it, and against the steam current, into the top of the boiler. The main in this system must be large, otherwise the water will not flow back in opposition to the current of steam, and then trouble will follow. Condensed steam does not flow back along the bottom of the pipes as you might suppose, but clings in drops all round the pipe by attraction, forming a considerable obstruction to the flow of steam. The radiators are supplied on the floor above by a single steam flow pipe from the main, large enough to carry back the condensed water from each radiator. This system is seldom adopted, and could only be used in a very small building with any chance of success or freedom from noise. In the second system the steam main from the boiler is carried direct to the highest point at the basement ceiling over the boiler, and thence with a gradual fall of, say, 1in. in 10ft. round the basement walls, returning to the boiler, which it enters below the water line. The radiators are fed by flow pipes off the main, the condensed water from them falling back through the steam flow pipes, and against the flow of steam, into the main, and flowing by gravitation back to the boiler in the same direction as the steam flows in the main, which is practically a part of the boiler. These are both one-pipe systems. In the third system, which is very often adopted, the steam main is carried direct to highest point under the basement ceiling and thence with gradual fall to the furthest point of the apparatus, where it drops to the floor level, and then under the water line of boiler becomes a return pipe to the boiler, conveying all condensed water back without loss. The radiators on the floors above are supplied with steam from the main

flow by a smaller flow pipe, and the condensed water is conveyed back from the radiators on the different floors by the same steam pipes, and against the current of steam, into the return main under the water line, all condensed water returning to the boiler by gravitation. This is also properly a one-pipe system, though it has a return main under the water line.

The fourth system is that generally adopted in good work and gives most satisfactory results. The steam main is carried at once to the highest point at the ceiling in the cellar over the boiler and graded thence to the furthest point, then dropping to the floor level and returning under the water line and up into the boiler. The radiators on the different floors are supplied with steam by flow pipes from the mains, but each radiator has a second or return pipe to carry off the condensed water separate from the inflowing steam. The various return pipes are joined into one return pipe, which drops into the return main under the water line. This is the two-pipe system. The fifth system is more elaborate and costly, and, therefore, seldom adopted. The steam mains and return mains are similar to the last, but every radiator has its own return pipe for condensed water, which is kept separate from the return of every other radiator above the water line, and is carried either direct into the return main or joined to the return of some other radiator below water line. By this arrangement there are as many return pipes as there are radiators, and the advantages gained are not sufficient to compensate for the extra cost and trouble. All radiators are provided with shut-off steam valves and with valves to provide for the escape of any air, for air in radiators checks the heating power.

In a paper of this kind there is not space for any extended advice about steam boilers, but we may note that in American practice cast-iron steam boilers are almost universally adopted for low-pressure heating installations. They are made in sections, very convenient indeed for carriage and for meeting the difficulties which arise when boiler pits are at the foot of narrow stairs or at the ends of narrow passages, or where doorways are contracted. The iron used for castings in America is of a special kind. The castings are usually very perfect, and the sections interchangeable, so that in the event of any accident to one section, or of one section burning through, it can be taken out and replaced quickly. The American engineers invariably maintain that cast-iron is more durable than wrought-iron, and that wrought-iron is more durable than steel, which oxidizes more readily. This view is somewhat different to that held by English engineers. In any case, although American boilers are tested to stand 100lbs. pressure per square inch, I would be disposed to place the outside limit of safety in use at 20lbs. of steam, and for heating I prefer not to exceed 10lbs. on any American cast-iron steam boiler. The sectional boilers are very sensitive and utilise the fuel to its full extent, heating up quickly and burning fuel thoroughly. Nearly all are supplied with rocking, self-cleansing grate-bars and economising fittings. In specifying American boilers it is usual to add in all cases 25 per cent. to the book rating as a margin of safety. If you are using direct indirect, that is, ventilating radiators, you may add another 25 per cent. to your rating in order to provide for the warming of the incoming cold fresh air. Manufacturers follow no standard in rating the power of their heating boilers.

Suppose, therefore, you have settled on 4,000ft. of radiating surface in your building; specify a boiler not rated for 4,000ft. but for 5,000ft., and, if you use ventilating radiators, specify a boiler rated for 6,000ft. and you will not be far wrong. Some sectional boilers have their sections connected with packed flanges and bolts and nuts, others by screwed nipples, and others by slip ferrules drawn into solid metallic contact by long iron screwed rods passed from end to end; the last are the most trustworthy.

The wrought-iron Cornish boiler made by reliable makers is one of the best forms for steam work, but it requires careful skilled setting in brickwork to secure good results, and before you specify your dimensions see

that your boiler can be got into position without too much labour or pulling down of walls, and take the advice of an experienced heating engineer. In roughly proportioning the size of such a boiler to your work, if your chimney draught is good with about one-sixth to one-eighth inch the area of your grate, you will not be far out in allowing 10 superficial square feet of boiler surface and $\frac{1}{2}$ sq. ft. of grate area to every 100 sq. ft. of radiating surface; but these proportions will vary with circumstances. Chimney flues are generally provided too small in area for heating boilers. You will do well to avoid that mistake, because proper combustion of your fuel depends on the areas of fire-grate and chimney being properly adjusted, and the economy in heating depends on the arrangement of boiler surface so as to absorb as much as possible of the heat. The more fuel you can burn under and absorb into your boiler at once the less will be your waste heat.

The sizes and arrangement of mains must be carefully considered and determined for every installation as much by practical experience as by standard formulae. You may, however, assume, as a guide for maximum dimensions of steam mains under any system, that the area of an inch pipe for every 100ft. of radiating surface will more than suffice, and that the area of a square inch will be sufficient for hot-water mains at ratio of 7854 to 1 respectively. In steam work one-pipe installations require larger mains than those on the two-pipe system. With experience in piping and with favourable conditions, smaller mains may be adopted. For instance, the radiating surface in many efficient jobs ranges as follows:—With 2in. mains, 400ft. to 600ft. of radiating surface; 3in., 900ft. to 1,200ft.; 4in., 1,500ft. to 2,000ft.; 5in., 2,500ft. to 3,500ft.; 6in., 3,500ft. to 5,000ft.

Strict adherence to the 1 sq. in. area rule in hot-water work is advisable, and it gives us in radiating surface the proportions of 350ft. for 2in., 750ft. for 3in., 1,250ft. for 4in., 2,000ft. for 5in., and 3,000ft. for 6in. mains.

You may keep in mind however that, except for the first cost, an installation will not be any the worse for having large mains and large boilers. Steam will then be able to show nearly the same pressure at the furthest radiator as on the boiler gauge. There are many other points connected with the arrangement of steam and hot-water heating apparatus, essential to the success and economy of every installation, such as provision for expansion and contraction safety valves, shut-off valves, regulators, &c., that we have no time to consider; these are really the business of the heating engineer. Water-hammer noises and want of easy regulation of temperature are the two main objections to steam heating, but the former can be eliminated by good design and proportion with proper manipulation of valves. The latter objection must stand more or less against all ordinary-pressure steam apparatus. You must have your valves full off or full on. In all steam apparatus friction and condensation will cause some loss of pressure in the parts furthest from the boiler. If the loss of steam pressure in a radiator is 1lb., then the water in the return pipe from that radiator will back up 2½ft.; with 2lbs. loss the water will back up 4½ft., and may flood the lower radiators, causing water-hammer noise. If the pressure were the same throughout, the level of water in the furthest return would stand at the level of the water in the boiler. The engineer will endeavour to proportion his piping so as to show the least difference of pressure throughout. In a system with long horizontal runs of main flow and return pipes this point must be well cared for, and the lowest point of the radiators placed as far above the water-line of the boiler as circumstances permit.

In the steam-heating apparatus which we have been considering we force the circulation of steam by maintaining sufficient pressure to drive the air (which is a serious obstruction to the circulation) out of the pipes and indicators. There is always more or less difficulty in doing this. The vacuum system of steam heating at and under atmospheric pressure is now used in America, and is being

* A paper read before the Architectural Association of Ireland on February 20th, 1900.

introduced slowly into this country. By this method the air is first drawn or sucked out of the pipes and radiators by mechanical action, creating a partial vacuum in the system, and it is only after this vacuum is produced that steam is admitted to the heating apparatus; and steam so used may be at or under atmospheric pressure. The vacuum system may be applied to any gravity steam apparatus; the ordinary radiators suffice. A second pipe large enough to carry the water of condensation is taken from each radiator, and is joined to a drop return pipe led down to the basement, where it is connected to a direct-acting vacuum air-pump, which creates a partial vacuum and at the same time draws off all condensed water from the radiators and system generally. An automatic valve is attached to the radiator at the bottom where the vacuum pipe joins. This valve is so constructed that as long as it is cold with air in contact, it remains full open; when hot steam reaches it the valve closes; and when condensed water comes in contact with it, it opens sufficiently to allow the water to pass, closing again when hot steam touches it. This system is known as the Webster system, and in large installations a great economy of fuel is effected. Exhaust steam from steam engines can be utilised without any back pressure on the engine cylinders; but we have all the disadvantages of mechanical appliances in the vacuum pumps to be kept in order. There is another system known as the Paul system in America. It can be adopted to any well-arranged one- or two-pipe steam gravity system as follows:—

An exhausting steam ejector is fitted in the cellar, and the radiators are connected with it by means of $\frac{1}{2}$ in. air-pipes attached to the air-valves of the radiators—condensed water is left to return to the boiler by whatever arrangement may have been previously adopted, either on the one- or two-pipe system. The steam ejector is turned on, and it removes the air from the radiators and pipes, creating a partial vacuum with great ease and rapidity. Into this vacuum the steam at or under the atmospheric pressure (i.e., steam at 200deg. to 212deg., showing no pressure whatever on the steam gauge) may be admitted, and it will flow into the pipes and radiators with far greater rapidity and ease than steam under corresponding pressure will flow into an ordinary apparatus full of air. For instance, if you create a vacuum of 5lbs. in your apparatus, and turn in steam at 212deg., under no apparent pressure, you get much better and quicker results than you could possibly obtain if, without the vacuum, you turned in steam under a pressure of 5lbs. over atmospheric pressure. Atmospheric pressure amounts to about 15lbs. per square inch. Steam gauges are marked to show only the pressure in excess of atmospheric pressure—if your steam gauge shows 5lbs. pressure it means 5lbs. over the atmospheric pressure, or 20lbs. in all.

Suppose we have 10,000 sq. ft. of radiation in an installation. It has been ascertained that 20 per cent. of the fuel can be saved by the vacuum, as compared with the ordinary gravity system of steam heating, and where exhaust steam from an engine is always available for heating (and now completely wasted) we may almost undertake to heat a building free of cost for fuel—all exhaust steam, now so frequently turned to waste, can be saved, purified, and utilised for heating without throwing away back pressure on the engine, which has hitherto been the chief drawback to its use. Any air left in the radiators reduces the effective heating power, and it is not easy to get all the air away in ordinary steam heating under low pressure; but in a vacuum system the maximum amount of air is removed and the maximum heating power gained, and all the foul air of the apparatus is sucked away and discharged outside the building, where the heavy odour is unperceived; it is not an agreeable odour to set free in a building at any time. In the Paul system the air is drawn from the radiators sufficiently high above the bottom to prevent the condensed water being drawn off by the same pipe. In the Webster system the air and condensed water are drawn off together

from the radiator at its lowest point. We will now briefly enumerate

Various Systems for Warming Buildings,

some apart from ventilation, and some combined with it.

First system: direct warming by radiation and convection from fuel in open fireplaces, grates, and hearths, combined with constant active extraction of air by the open flues of the chimney. This system radiates the heat in straight lines to the floor, walls, and surrounding objects, the warmed surface of which in due course convey the heat to the air. This is our English system, and air in the building is never injured by overheating, but draughts are developed across the floor towards the fireplace unless air inlets are specially arranged.

Second system: direct warming by radiation and convection from fuel in closed stoves placed within the building. By this system iron smoke-flues may be utilised to increase the heating power of the stoves; care is required to prevent the quality of the air being deteriorated by overheating of the heated surface or by any escape of gas from the furnace.

Third system: indirect warming by convection from fuel in furnace located in underground heating chambers, columns of fresh air passing over the heated surfaces in the heating chamber. In these systems the furnaces are highly heated, and the salubrity of the building depends on the abundance of the volume of fresh warmed air admitted on the natural system of ventilation.

Fourth system: indirect warming, by convection, by furnaces in underground chambers, accompanied by a system of mechanical extraction of vitiated air from the building, causing a vacuum to draw in the fresh warmed air rapidly on the exhaust method of ventilation.

Fifth system: indirect warming by convection, by furnaces in underground chambers, accompanied by a system of combined mechanical propulsion and extraction, both to draw off vitiated air and to force in large volumes of fresh warmed air to the building, on the combined Plenum and exhaust method of ventilation.

Sixth system: direct warming by radiation and convection from high-pressure hot-water apparatus arranged in small bore wrought-iron pipes and coils within the building, the heat being raised by fuel under a boiler formed of a coil of the same iron piping arranged in a furnace. There are two arrangements of this system—(A) the hermetically sealed arrangement, in which expansive air chambers are provided to allow the necessary means of expansion for the heated water; (B) the safety or double safety arrangement, in which a self-acting valve or valves placed in the water-supply cistern provide the necessary means of expansion for the heated water.

Seventh system: indirect warming by convection from high-pressure small-bore hot-water apparatus, arranged in pipes and coils in one or more heating chambers, combined with a natural flow of fresh air through the heating-chambers, delivered through gratings and channels to the building on the natural method of ventilation.

Eighth system: indirect warming by convection from high-pressure hot-water apparatus in heating chambers, combined with a mechanical system of propulsion of fresh warmed air into the building on the Plenum method of ventilation.

Ninth system: indirect warming by convection from high-pressure hot-water apparatus in heating chambers, combined with a mechanical system of extraction of vitiated air from the building, causing a vacuum to be supplied by fresh warmed air drawn into the building on the exhaust method of ventilation.

Tenth system: indirect warming by convection from high-pressure hot-water apparatus in heating chambers, combining propulsion inwards of fresh warmed air and mechanical extraction outwards of vitiated air on the combined Plenum and exhaust method of ventilation.

Eleventh system: direct warming by radiation

and convection from medium-pressure hot-water apparatus arranged in small-bore wrought-iron pipes and coils with direct radiators within the building, the heat being raised by fuel under a boiler formed by a coil of piping, or by any other form of boiler capable of withstanding twice the pressure that the apparatus can possibly be exposed to. The water circulation by gravitation at a temperature higher than in the low-pressure system, but never rising to an excessive degree.

Twelfth system: direct and indirect warming by radiation and convection from medium-pressure hot-water apparatus arranged in small-bore wrought-iron pipes and coils and boiler, with direct indirect radiators drawing in the fresh air from without and delivering it warmed to the building on the natural method of ventilation.

Thirteenth system: direct warming by radiation and convection from low-pressure hot-water apparatus arranged in pipes and radiators within the building, the heat being raised by fuel under a low-pressure hot-water boiler, and the heated water conveyed in pipes by gravitation through the building.

Fourteenth system: indirect warming by convection from low-pressure hot-water apparatus arranged in pipes and batteries in one or more heating chambers, combined with a flow of fresh air through the heating chambers, delivered through the gratings and channels to the building on the natural method of ventilation.

Fifteenth system: indirect warming by convection from low-pressure hot-water apparatus in heating chambers, combined with a mechanical system of propulsion of fresh warmed air into the building on the Plenum method of ventilation.

Sixteenth system: indirect warming by convection from low-pressure hot-water apparatus in heating chambers, combined with a mechanical system of extraction of vitiated air from the building, causing vacuum to be supplied by fresh warmed air drawn into the building on the exhaust system of ventilation.

Seventeenth system: direct warming by convection from low-pressure hot-water apparatus in heating chambers, combining mechanical propulsion inwards of fresh air and mechanical extraction outwards of vitiated air on the combined Plenum and exhaust method of ventilation.

Eighteenth system: warming by radiation and convection from injection low-pressure hot-water apparatus arranged in pipes and radiators within the building, and to be heated by special silent steam injectors through one or more circuits from a steam boiler. Direct indirect radiators may be used with advantage, admitting fresh warmed air to the building on the natural method of ventilation.

Nineteenth system: direct warming by radiation and convection from steam heated low-pressure hot-water apparatus arranged in pipes and radiators within the building in various suitable independent circuits, each circuit heated by a calorifier (usually a closed cylinder of copper with a coil of heavy copper steam pipe within, carrying highly-heated steam under pressure from 10lb. to 100lb., which rapidly heats the water in the calorifier and starts rapid circulation throughout its own circuit). The steam is taken from any central steam boiler under sufficient pressure, and the condensed steam carried back by gravitation into the steam boiler to avoid waste. Direct indirect radiators may be used with advantage, admitting fresh warmed air to the building on the natural method of ventilation, and this may be accompanied by mechanical extraction of vitiated air on the exhaust system of ventilation.

Twentieth system: direct warming by radiation and convection from two-pipe low-pressure gravitation return steam apparatus arranged with pipes and radiators within the building, with main pipes, supply, steam, and return water pipes, to convey the steam supplied from a steam boiler, all condensed water flowing by gravitation back to the generator; the apparatus arranged to work at steam pressure of from 5lb. to 10lb.

Twenty-first system: direct warming by

radiation and convection from single-pipe low-pressure steam apparatus arranged with direct radiators in the building, and one steam main from the steam generator, condensed water returning to the generator through the steam main; suitable only for small buildings, with the radiators one above another, where long horizontal runs of pipe are not required.

Twenty-second system: direct warming by radiation and convection from double-pipe low-pressure steam apparatus, with gravitation return arranged with pipes and direct indirect radiators within the building, with main pipes, steam supply from and condensed water return pipes to steam boiler. The radiators arranged to admit a flow of fresh warmed air to the building for ventilation by natural method.

Twenty-third system: direct indirect warming by radiation and convection from single-pipe low-pressure steam apparatus, arranged with direct indirect radiators in the building, and one steam main from steam generator, condensed water returning to generator through the steam main; suitable for small building, with radiators one above another where long runs of horizontal pipe are not required. The radiators arranged to admit a flow of fresh warmed air to the building for ventilation on natural method of ventilation.

Twenty-fourth system: same as twenty-third, accompanied by a system of mechanical extraction of vitiated air from the building, causing a vacuum to draw in the fresh warmed air rapidly on the exhaust method of ventilation.

Twenty-fifth system: same as twenty-fourth, accompanied by a system of mechanical extraction of vitiated air from the building, causing a vacuum to draw in the fresh warmed air rapidly on the exhaust method of ventilation.

Twenty-sixth system: indirect warming by convection from low or high-pressure steam apparatus, arranged in batteries in one or more heating chambers, combined with natural flow of air through the heating chambers, delivered through the gratings and channels to the buildings on the natural method of ventilation.

Twenty-seventh system: indirect warming by convection from low or high-pressure steam apparatus in heating chambers, combined with a mechanical system of propulsion of fresh warmed air into the building on the Plenum method of ventilation.

Twenty-eighth system: indirect warming by convection from a low- or high-pressure steam apparatus in heating chamber, combined with a mechanical system of extraction of vitiated air from the building, causing a vacuum to be supplied by fresh warmed air drawn into the building on the exhaust method of ventilation.

Twenty-ninth system: indirect warming by convection from high- or low-pressure steam apparatus in the heating chambers, combining mechanical propulsion inwards of fresh warmed air and mechanical extraction outwards of vitiated air on the combined Plenum and exhaust method of ventilation.

There are also the systems of heating by steam at or under atmospheric pressure, by live or exhaust steam, as already described, with or without ventilation. Indirect warming systems may be combined with direct warming systems by placing radiators giving out radiant heat in any desired portions of the building. Indirect systems of warming should be provided with arrangements to reduce at will the temperature of the air sent into the building, without lessening the volume of air supplied. The control of temperature should be placed in the hands of the engineer or caretaker, and should not be subject to the whims of individuals. In a perfect system of combined warming and ventilation for large asylums, hospitals, colleges, schools, &c., great care must be taken to insure an abundant supply of pure air, which should be taken from some point well above ground level, and well away from the building and from all sources of impurity. Screens for filtering the air, when used at all, must be very readily and frequently cleansed, else they soon become worse than useless, giving back impurities to the passing air when they become subcharged.

In conclusion I would like to say a word on behalf of the heating contractor which may prove useful to all connected with the profession, young architects especially; always remember the dignity of the profession and the old French proverb which says *that noblesse oblige*. Do not be too hard on your contractor. No doubt you will often have a difficult position to fill as mediator between your client and the contractors, but try not only to be as just but as generous as your client ought to be, and, while seeing that your contractor carries out his contract honestly, remember all the difficulties that lie in his path and help him over them as they arise, patiently and kindly if you can. Be the "daysman to lay your hand on both" and keep them together in friendly concord. My own experience furnishes me with many memories of the helpful kindness of members of your profession. How gratefully I recall the names and the features of many who have gone from us, many whose kindly faces you never saw, whose courteous voices you never heard. A great change has passed over your clients during the last fifty years, and I doubt if it be for the better. The writer remembers so well the marked kindness and consideration invariably shown to contractors, but if the changes in the condition of people have lessened the general tone of consideration for others in business dealings, architects have special opportunities of fostering that happy spirit. Especially when limited or not limited tenders are called for in competition, they can see that the conditions are just and that the contractors invited to compete are treated as if they were honest and respectable gentlemen, with a full measure of courtesy, and are afforded every possible facility and information, providing specification, bills of quantities, without cost or needless trouble to the competitors, unless they are to be remunerated in some way. You as considerate, kindly architects will bear in mind that the engineers and contractors for artificial heating invited to your offices have hard work to do and little time to spare; that if they are called on for plans and tenders in competition free of charge, it is a mere chance whether they get the work; and that they must lay other work aside in order to attend to this new demand on their time and brain power; and therefore kindly consideration will be shown, appointments will be punctually kept, and every possible explanation and facility will be courteously given. Contractors greatly appreciate this spirit in architects, but avoid offices where it does not exist.

Then during the progress of the work every aid will be extended to the contractor; he will be treated as an accepted assistant, rather than a suspected conspirator, and when the work is done, necessary tests will be promptly applied, and the final certificate will not be held back unless good reasons exist. The contractor pays his workmen wages week by week, and wants his money; you may be quite certain of that. "The labourer is worthy of his hire," and ought to get it, too! Then, when all is done, the worthy architect will not forget the contractor who has carried out his work well, and will be ready to recommend and prefer him for future contracts, as proof of his approval, and as his fairly earned reward. Business can be both profitably and pleasantly done when architect and contractor show such mutual consideration, and you may depend upon this, that the highest in the land lose nothing by deserving the good word and good opinion of the lowest.

Belfast Technical Institute.—The Council of the County Borough of Belfast has decided to acquire a portion of the Royal Academical Institution grounds as a site for the proposed technical institute.

New Buildings at the Mint.—It is stated that the new die and metal department which is to be erected at the Mint will cost £8,500. The buildings of the Mint were erected in 1805-10 from the designs of Johnson and Smirke, but the operative department underwent entire reconstruction in 1881-2.

EARLY GREEK CIVILIZATION.

MR. CHARLES WALDSTEIN, Litt.D., Ph.D., L.H.D., Slade Professor of Fine Art at Cambridge, gave last Thursday afternoon, at the Royal Institution, Albemarle Street, W., the second of a series of three lectures on "Recent Excavations at the Argive Heraeum in Greece"; the first lecture was reported in our last week's issue. The lecturer pointed out that within the last twenty-five years there had been a marked revolution in views held by archaeologists and historians in respect to the earliest Greek civilization and art. The archaeologists of the older generation had made two mistakes—in regarding as the earliest products of Greek art statues which we should now not dare to place before the ninth or eighth centuries B.C., and in attaching too much importance to the Homeric poems as affording proper indices for the study of early Greek civilization. Students were now realising more and more that the poems marked the end, not the beginning of a civilization and presupposed long stages of anterior evolution. Since Schliemann began his work about twenty-five years ago a new period—the Mycenaean—had been firmly established, grouping round 1500 B.C. It was also realised that this gradually died out and failed about 1450 B.C., and was succeeded by a new and lower civilization beginning with the inroad of the Dorians—a kind of dark Middle Ages grouping round 1100 B.C.—and then a kind of Orientalising influence came in and led up to the highest archaic Greek civilization and art. In regard to these views the site of the Argive Heraeum was of the greatest interest.

It was undoubtedly in Hellas proper that the earliest beginnings of Greek civilization began, and for this reason he attached such importance to the Argive Heraeum, as it was not open to the objections that Hissarlik (Troy), Mycenae, or Tiryns were on the score of not being in Greece proper. The importance of the Mycenaean period had been exaggerated and scholars had supposed it to be the beginning of a Greek civilization, while admitting the existence of an earlier life to which they refused the title Hellenic. But, in the lecturer's opinion, it was necessary to go further back still, and assume that before the Mycenaean period there were at least three centuries of civilization on the Argive plain Hellenic in character and continuous in development. This theory was supported by evidence drawn from topographical and architectural considerations, from mythology and from literary tradition. He was inclined to put the date of the remains of the early temple he had referred to in his first lecture at 1830 B.C., and Mr. F. C. Penrose, who combined astronomy with his studies in archaeology, gave the same date to it from the consideration of its orientation, based upon calculations he had made, tending to show that the orientation of temples erected at various times changed with the position a certain star occupied.

The development of this early art referred to was illustrated by the terra-cottas found on the site; the earliest of these could be classified into eight or nine different types, several of which antedated the Mycenaean period. As regards continuity of development, the lecturer pointed out that Mycenaean art, distinguished by the introduction of glazed colours, by its freehand drawing, and by the naturalistic character of its design, was succeeded by a period of mere geometrical mechanical ornamentation, which, again, was followed by the proto-Corinthian with linear designs. This linear ornamentation had been regarded as being in contradistinction to the naturalistic feeling which was held to be Hellenic, but he considered that the linear was the earliest principle of design, and that it could be traced concurrently with the other, in vases, &c., right through the Mycenaean period from the early beginnings of Greek art. Many photographs were shown in illustration of the various points dealt with in the lecture.

ARCHITECTURAL ASSOCIATION.

SMALL HOUSES.

By C. E. BATEMAN, F.R.I.B.A.

A MEETING of the Architectural Association took place last Friday, Mr. G. H. Fellows Pryne, the president, occupying the chair. The minutes having been read and confirmed, the following gentlemen were unanimously elected members of the Association:—Messrs. R. E. Hemingway, J. A. Jones, A. G. R. Mackenzie and F. Nichols. On the proposition of Mr. R. S. Balfour, hon. secretary, a vote of thanks was then accorded to Mr. W. E. Riley, superintendent architect to the London County Council, for his courtesy on the occasion of the second Spring Visit of the members of the Association to the new artisans' dwellings on the Millbank Estate.

9ft. 3in., and 12ft. by 10ft. 6in.; bath-linen cupboard.

Ground Floor Area, 944ft. super. at 15s. 10d.=£750

Cost, £750 at 5½ per cent.=£39 7s. 6d.
Ground Rent at 2s. a yard = £5 10s. 0d.

£44 17s. 6d.

Rent obtained, £45.

Higher limit.—For the higher limit I also give from an actual example the following accommodation:—Entrance; cloak-recess; hall, 14ft. by 14ft.; drawing-room, 18ft. by 14ft.; bay and ingle, 4ft. 6in. by 8ft.; dining-room, 21ft. by 14ft. 6in.; service door billiard-room, 22ft. by 17ft.; bay and recesses; lavatory; pantry, 14ft. by 7ft.; wine cupboard under stairs; servants' sitting-room, 14ft. by 12ft.; working kitchen, 14ft. by 14ft.; sink, back stairs, trade entrance, larder, servants' yard and covered way to coals, ashes, knives, boots, and water-closet. Bedrooms over hall, dining-room and drawing-room, two over billiard-room; dressing-room over entrance; two rooms over kitchens; box-room

better, and the more certain the interest on outlay. The character and surroundings of the land should govern the character of the house, and it requires restraint not to put too good a house on the land. It requires the genius of the speculating builder to obtain more than six per cent. interest on the outlay, and this is difficult to get. The question of outlay must receive our consideration, because a man cannot live at a higher rental than a certain proportion of his income, which some put down at one-tenth. One also must take into consideration the change in fashion and depreciation upon a change of tenancy or ownership.

Economy, of necessity, is of the utmost importance, oftentimes with advantages, as more houses are spoilt by having too much money badly spent upon them than too little; fortunately for us, a client does not always look to his house to be one of his most saleable investments, but nevertheless it must be one of his available assets.

Birmingham, like many large towns of recent growth, has little or no available land near its centre for residences, as it is more valu-

A COITAGE FOR MR. C. A. HARRISON AT BARNT GREEN. BATEMAN AND BATEMAN, ARCHITECTS

It was then announced that a special meeting would be held on March 23rd, before the general meeting, to put before the members some suggested verbal alterations in the by-laws. Mr. C. E. Bateman, F.R.I.B.A., then read his paper on "Small Houses" as follows:—

My remarks are supposed to apply to houses between the limits of, say, £800 and £2,500, which down in the country is the most usual class we have to deal with.

The following is the accommodation of an actual example of the lower limit:—

Lower Limit.—Porch and lobby; two sitting rooms, 17ft. by 13ft.; pantry; larder; wine cupboard; kitchen; scullery; coals; ashes; water-closet; five bedrooms—13ft. 6in. by 13ft. 6in., 12ft. by 13ft., 13ft. by 10ft. 6in., 13ft. 6in. by

over larder; bath-room and water-closet; stables extra and electric light.

Ground Floor Area:

House ... 2,317ft. super.
Outbuildings ... 173ft. super.
Stables ... 836ft. super.

Upper Floor ... 3,326ft. super. at 14s.=£2,324
... 2,263ft. super.

5,589ft. super. at 8s. 4d.=£2,325

Cube:

House ... 61,851ft. at 7½d.=£1,935
Outbuildings ... 2,249ft. at 6d.= 60
Stables ... 13,537ft. at 6d.= 336

Total 77,637

Contract price £2,325.
Ground Rent at 2s. per yard £50.

As a general rule, the smaller the house the

able for business purposes and workmen's dwellings; the distance, therefore, has to be bridged over by rail, tramway, or omnibus. These conditions, I suppose, apply to other great towns. This may seem an unimportant matter, but when a man is engaged in some business which leaves him free for a couple of hours in the middle of the day, he often takes the opportunity of going home for luncheon. It is therefore important that the house should be so disposed that the cooking and service arrangements may be such that he can return to his business in a fairly good temper after taking his midday meal. In Birmingham there is very little or no freehold land; it is practically all in estates which only grant leases. This, perhaps, militates in some

degree against substantial construction, but a certain control is exercised which improves the class of building if a competent surveyor is in charge, and who examines the plans submitted for approval.

The effect of the leasehold system on building is a very vexed question and scarcely comes within our province this evening, although it has a general bearing, but a client will generally build rather a stronger and better house upon freehold land.

Points which force themselves upon us when laying down a plan are the approach to the land, the aspect, the views obtainable and the levels, the most important perhaps being the aspect. Every ray of sunshine should be made available. No house can be considered satisfactory which cannot warm itself and its occupants with the sun as it passes or appears to pass, from east and west; and too much stress cannot be laid upon this fundamental and important consideration. It is easy enough to shut out too much sun, but it is impossible to obtain the sunshine if the rooms are placed on the wrong side of the house. When advising upon the selection of a site keep this well in mind, for should the sun, the views, and the fall in the land be all in one direction, half our troubles are at an end. The most difficult place to arrange is where the approach and the front door, of necessity, come on the south-east, for the reason that the dining-room, being of course placed south-east so as to have sunshine for breakfast and luncheon, the front door has to be placed southward or eastward of it. If eastward, the entrance has to be crossed by the service from the kitchen; and if southward, servants have a long distance to go round the dining-room to admit visitors.

I think you will agree with me that a western aspect is bad for a dining-room, because the evening meal for more than half the year is taken by lamplight, and no direct sunlight is upon the room for breakfast, and very little for luncheon.

While upon the question of approach, I should advise that porches placed in an internal angle, with the doorway on the diagonal, should be avoided, as they are very difficult to drive up to. Porches are not easy to treat, as, when small and of the usual type, they seem to be stuck on, and to have the character of the dog kennel or furniture van. When large enough and two storeys high, they certainly look better, but are expensive, and I am inclined to think the recessed porch is cheaper, while it gives scale to a small house, and forms in the hall a convenient bay-window recess. The space over the top of the door may form a useful cupboard for rugs, tennis rackets, &c.

After having considered the possibilities of the site, with its aspects and approach, the next point will be to determine the number of stories required to contain the accommodation. In the country, basement kitchens are not advisable, as no servants can be kept where they are not on the level. In fact, avoid cellars as much as possible as they entail considerable outlay for a provision which is rarely or little used, while, for the smaller class of house under consideration, sufficient space for wine or beer may generally be found under the staircase by going down three or four steps to the bottom of the footings.

Having disposed of the cellars the ground plan will now receive our attention, but we must not get too much wedded to a particular arrangement without carefully considering the bedroom floor and the roof plan. This latter is so all-important, not only from the nature of our climate and on account of the capacity of attics for containing bedrooms but also from the effect it produces in external appearance, so that the roof in a great measure governs the plan itself and unless it seems to ride comfortably on the walls and with its spans intersecting easily and simply into one another the general harmony and homogeneous character of the whole block will be spoilt.

I have found a space of 17ft. will give useful attics by placing the joists underneath the wall plate, and by carrying them through and spiking them to the feet of the rafters a good tie is obtained. Stud up to the rafters with

the intersection 4ft. from the floor and place the purlins above the ceiling joists at the intersection with the rafters, and you will have a strong, rigid and economical roof.

Trussed purlins are very useful, as forming the sides of the attics and will often be found more convenient than principals, especially in wide spans, as the sill piece can be used as the bearer for the attic joists and the wall plate be kept to 7ft. from the first floor. I generally use 4½in. by 3in. rafters placed 16in. centre to centre, with 11in. by 4in. purlins, and plates 9in. or 11in. wide. This latter, I think, is a wise precaution, especially in 11in. hollow walls, as support is thus obtained from the inner as well as the outer 4½in. of the brick-work.

Boarding the roofs gives an additional strength, and, although it raises the cost, it makes the attics much warmer, and, if you have slept in attics all your life, as I have done, you will realise this advantage. If boarding cannot be adopted, Willesden paper is a useful substitute, and should be placed on the top of the rafters with an additional intermediate lath, the whole torched up solid as the tiles are put on, to keep the fine driving snow from getting in and to keep out the draught.

As regards roof coverings, I suppose it will be agreed that stone slates from Northamptonshire and the Cotswold Hills are without doubt the best, not only from their strength and lasting qualities, but also for their appearance. They require to be carefully laid in the first instance, as they are not easily repaired, except by men from the district where they are obtained; in fact, men used to handling the Colleyweston slates cannot lay those from the Cotswolds, and vice versa. The Colleyweston slates are pointed, and the Cotswolds are not. The cost comes out to about 20s. to 30s. a square more than tiles, which mounts up; but they are worth a sacrifice to obtain. An example may be seen at Mr. Peto's house in Harrington Gardens, and of course every one is familiar with them who knows Oxford. If stone ridges cannot be used, buff-coloured tile ridges look the best. Tiles make a roof warmer than slates, and where sound old ones can be obtained they look all the better for being weathered. Most of our modern tiles will not change colour, or, if they do, go black all of a piece, which is as bad. The smooth surface due to the machine pressing used in their manufacture accounts somewhat for this; but they are also very much thinner than the old ones, causing the roof lines to look hard for the roofs. Half-round ridge tiles are preferable, perhaps, to those with ornamental tops.

Fortunately green slates are more easily obtainable than formerly, and the cost of those from Llandilo, in South Wales, is not so very great. I have tried the experiment of laying them in narrow courses, the long way of the slates going in the same direction as the laths; in this way they come more in the proportion of tiles and with a pleasing effect. Never use a red ridge with green slates; a blue ridge makes a much softer finish against the sky. There has been of late years a crusade against slates, and the purple-coloured Bangors are certainly uncompromising with red bricks, but the blue-grey upon whitewashed brick-work or rough cast are not so objectionable. If hips are introduced, make the ends steeper by lengthening the ridge 3ft. or 4ft. so as to correct the dropping effect where seen on the diagonal. This necessitates altering the gauge of the laths, but it is not a difficult matter.

Before leaving the roofs a word might be said about lead, but owing to its cost it has to be used very sparingly. In a small, cheap house parapets and lead gutters are out of the question, and one often has to use cement flashings to chimneys where tiles are employed. Cement, however, will not always adhere to the smooth pressed tiles without they are chipped. As lead work is expensive, one must not have too many dormers, and it is not easy to design a house without dormers or gutters, in fact, it is difficult but is a useful exercise, as these are two of the points where snow and wet may most easily get in.

Zinc is a poor substitute for lead and its

life is very short, especially when exposed to the effects of atmosphere containing chemical acids, though in the country, and if of strong gauge, it may be used with care.

Running the roofs over the walls of gables always seems the most practical and simple way of keeping the wall dry, while it saves a flashing, but there is a peculiar charm about coped gable, which marks the verticality of the gable in contrast to the horizontal line of the eaves. When a soft stone like Bath is used, the coping should be laid on a damp course of slates or asphalt and run out, instead of having kneelers, as the water running down is interrupted here, soaks through the stone, and appears in the room. When this method is adopted, a flat back section about 4in. thick with a good overhang is the best.

Hard bricks on edge with a tile creasing will keep out the wet; but in this case kneelers must be arranged, or else the bricks slip off, unless clip irons are used, in which case they are apt to look as if they would tumble off.

As to the projection of eaves, unless the soffits are plastered, they look thin if projecting more than 9in. to the back of the spout. Gardeners do not like a large projection, as the wall-creepers get little or no rain upon them. This goes to show that eaves keep the walls dry. When arranging the eaves and spouting look out for opening casements; it is trying to find that the windows won't open more than 6in. or 9in. Half-round eaves-spouts are as good as any. There is a good deal of difference of opinion as to whether chimneys on inside or on the outside walls make the rooms the most warm. Those in favour of inside stacks say that all the heat is thus conserved, while others maintain that an outside wall is cold unless it has a chimney in it. A safe way is to put some inside and some out, this being the arrangement that looks the best; and it is advisable for appearance to have as few large and high chimneys as possible, as the external facing is increased by multiplying the stacks, while they always look shorter and smaller in the work than on the drawings. Chimneys should be looked upon as miniature towers, not stalks. The roof and chimney design, with the general grouping, will often make or mar a house.

The term bungalow has had a good run for some time, but it is misleading; a house with simply a large and spreading roof is not, of necessity, a bungalow, and I doubt if it is an economical treatment, while it savours somewhat of affectation.

There is not much to be learnt from old houses about the planning of the bedroom floor, as in these the majority of the rooms lead out of one another and there are no original sanitary arrangements. These are points which would be considered serious defects in a modern house. One can, however, learn a great deal from them in the treatment of their plaster ceilings, to be seen not only in the best bedrooms but also in the attics. Chastleton, in Oxfordshire, and Daneway, in Gloucestershire, may be given as good examples. Iron casements are still expensive, and if many are inserted the price runs up, two opening casements, and often only one, are quite sufficient in a window; two hollows run round the edge of wooden casements will keep the wet from driving through in exposed situations. It is not often that one can avoid lath and plaster partitions, as the number of bedrooms cannot be obtained in a two-storey house by simply carrying up the walls. They are, however, a great nuisance, as they invariably both crack from the shrinkage of the timber and also more especially when carrying any portion of the roof. This has been recognised in one estate near Birmingham, where the surveyor declines to pass plans where they are shown. If open ceilings are adopted for the ground-floor rooms, it is very difficult to introduce rolled iron joists to carry the walls. The use of expanded metal lathing would, I think, avoid some of the cracking, but the intersection of the partition with the wall is the point where the greatest difficulty occurs. 17ft. by 13ft. is a very workable size for a bedroom, while 10ft. wide is about the minimum for comfort.

As to internal plumbing, it is hopeless to say anything about sanitary fittings as they are changing every day, but a combined iron bath and lavatory, known as the Brampton, is a useful arrangement. For water-closets, I prefer the lead traps to the basins, as there is less fear of breakage at the joint with the soil pipe. In order to avoid flooding from the freezing of pipes, expose and fix them all on wooden grounds on the top of the plaster; this keeps them clear of the brickwork, while a gas jet or lamp in the water-closet will keep the flushing-tank from freezing. Round circulating tanks seem to work the best and are the strongest. If these can be placed in a cupboard off the passage instead of in the bath-room the linen is not affected by the steam from the bath and can be got out when the bath is being used, while the passage may be to some extent warmed. It is, I presume, unnecessary to point out the great disadvantage of ever putting the bath-room and w.c. over a living-room, not only because of a possible collapse but also because of the nuisance arising from the noise. Provision should be made for stopping the supply with stop-taps, say near the scullery sink, if that is where the main covers in, as then the scullery tap will empty the pipe. A stop valve fixed just behind the ball valve will facilitate taking off for repairs in the w.c. A scouring joint to empty the kitchen back boilers, in case of repairs, must not be overlooked.

When arranging the staircase remember that elderly people will have to use it. Upon the recommendation of the coroner, no staircase is passed in Birmingham without a hand or wall rail. It is also well to bear in mind that sometimes coffins have to be carried down the stairs, and that it is unseemly to have carpenters in the house to break up the stairs or for the coffin to be let down through a window. The position of the staircase frequently dominates the arrangement of a plan, especially when we have attics. For this reason a T-shaped plan is often convenient, as the stairs will then land in the centre of the attics, avoiding passages, which are almost impossible to arrange owing to the want of head room under the rafters and particularly under the valleys. If stairs are carried up between walls, 3ft. 9in. is about a minimum width. These walls can be wrought framed up with 7in. by 2½in. timber and plastered between with good effect. Thick cords run through ring brackets are more agreeable than wall rails. For open stairs and landings saw-cut balusters and panels of ¾in. square bars in pattern are a pleasant change and inexpensive if not over elaborate. Many handrails are spoilt by being over moulded, which makes them uncomfortable to the touch. The nosing to the steps is best flat-rounder on the top side so as to avoid cutting the stair-carpet. 3½in. or 4in. square newels, carried up to the ceiling, help to support trimmers and beams, and appear to enclose the stairs and give you more for the money than turned oak newels. To place the staircase in the middle of the plan saves passages, as the bedrooms can be entered from all round the landing, but for light and ventilation a staircase against an outside wall is better; borrowed light through doors and screens is a poor substitute for direct window light. The starting of the stairs is often better out of sight of the front door, and if planned to lead out of a lobby instead of directly from the hall the latter can be made a more comfortable sitting-room. Owing to the number of doors in a hall there is, of necessity, a certain amount of draught. The sitting hall and ingle are often applied to houses which are really not big enough to receive them; hence they are terribly cramped, or else other points have been so sacrificed to obtain them that the balance comes on the wrong side.

A sitting-hall gives a certain spaciousness on entering, but it is not of much use unless it is, say, 12ft. by 15ft. with the staircase shut off from it. Ingle nooks want to be at least 4ft. 6in. deep from the face of the opening to the chimney breast, so as to admit of two persons sitting at the side, and they should be 9ft. or 10ft. wide, to save

scorching their clothes. I am not certain if fixed seats are so good as saddle-back chairs. We have all, I suppose, met with the difficulty of getting dog grates to draw properly, and I shall be glad to hear if anyone has found a remedy for their smoking. I think it is a good plan to narrow the opening to the flue from back to front, bringing it over and taking it back again higher up, the opening to the flue being 6in. or 9in. from back to front. Very sharp twists are bad, but gradual and easy bends are a help; lining the flues with 10in. pipes is a good practice, but expensive. I am inclined to think that the position of doors and windows and the direction of the draughts has a good deal to do with causing chimneys to smoke. One may generally rely on most of the flues going badly for the first twelve months, until they get dry, when pots may be added as necessary, and it will be well to keep these of varying heights, which sometimes prevents the smoke from one flue being drawn down an unused flue adjoining it. Nine-inch square flues are too small, as the clogging of the soot, which hardens and will not brush out, must be taken into account. I much prefer stone or marble chimney-pieces, because they then come into the contract and are put in as the work goes up, avoiding the stock pattern which we are compelled so often to adopt. I think a red stone, if it is of a bright colour, perhaps, looks best. A good builder will make the wood chimney-pieces just as well as anybody else, and, although it saves trouble to go to a specialist, the stock-pattern effect is nearly always obvious.

In arranging the lighting of the rooms, a discount for curtains and blinds should be allowed for. If mullion windows are adopted one light extra should be provided to meet this loss. In spacing out, 1ft. 6in. to 1ft. 8in. centre to centre works well for 4½in. by 3in. wood, and for light stone mullions, while 1ft. 10in. is the limit for 10in. by 5in. moulded stone mullions; 6½ and 4½ is a good section for a square stone mullion. When Bath is used and carefully sawn, it requires little labour upon it; at any rate, do not permit the drag tool or comb to be used. Heads and sills are best not less than three courses of bricks deep, except for very small windows. Avoid getting the jamb stones of only two dimensions where toothing into the brickwork; vary their length as much as possible to avoid a mechanical appearance.

Sash windows are perhaps the most draught-proof and water-tight, particularly as they are not usually filled with lead lights, but they govern to a large extent the character of the elevation and are not always admissible. It is also a question if the slight inlet of air through lead lights—that is, supposing them to be of good quality—is not an advantage in ventilation, especially where the rooms are low.

Thick leads and two, or at most three, panes of glass in width to the light are better than very small squares. Put in plenty of saddle-bars, as cleaning the windows cracks the joints and lets in the wet; ¾in. bars are not even. Bay windows to be of any use want to be big enough; two canted angles at the ends are better than only one, and a step up into the bay gives an elevation to the seat which is agreeable when looking through the window or down into the room.

Low wide windows perhaps light a room most agreeably and prevent the sun's rays from penetrating too far into the room in the summer when the sun is higher than it is in the winter.

In housework joinery is an important trade, but owing to the small stock of timber kept in country places—and often in any town for the matter of that—it is difficult to get it good. The mechanical processes of drying now in vogue are a poor exchange for the old-time method and for this reason large panels have to be avoided, except under special circumstances; pitch-pine is liable to split, and if used is better unstained. Square-framed doors are really quite good enough. When the panels are thick, in order to prevent weakening the styles, have the edges of the panels double rebated. Owing to the smallness of our rooms it is a great advantage to arrange them so that they can be thrown together by using folding doors. If you set the hall in the middle and can throw

the room into it on each side you obtain quite a big and interesting room for special occasions. Sliding doors for this purpose are a nuisance, and folding them back like shutters is as good a way as any, but look out for the projection of mouldings, skirtings and lock furniture, and use projecting butts. These doors want to be higher than the ordinary doors, which will do 6ft. 6in. or 6ft. 3in. by 3ft. or 3ft. 3in. Ledged doors in two heights or stable doors are nice for the entrance, as the upper portion can remain open in warm weather, and the porch is a pleasant place to sit in. Ploughed and tongued floors are necessary on the ground floor for warmth; these, of course, must be ventilated underneath, and iron sliding gratings are best, because of being under control. Open timber ceilings look very nice, but they are dreadfully noisy; if you do use them, put two thicknesses of floor boards and two thicknesses of felt, with inch strips between to make a cavity. For a room 17ft. by 13ft. two beams, 9in. by 7in., laid flat, will be sufficient, with 5½in. by 3in. joists, also flat, stumped into the beams at 16in. centres. If you lay the joists on the top of the beams and plaster the under side, put a small wood mould at the intersection of the plaster and the beam, to cover the subsequent crack which will arise from shrinkage.

A point that comes under our notice on the job is the way in which a 4½in. wall gets cut about by the ends of the joists of the floors, leading to a settlement and probable collapse some day. A course of bricks laid on edge across the wall makes a corbel table and gets rid of the difficulty. Proper fittings in the pantry, larder, kitchen and scullery add a good deal of comfort to a house. Pantry dressers are usually made 1ft. 6in. wide and 2ft. at the wash-up portion, and 2ft. 10in. high from the floor, with cupboards having two shelves, and drawers about 5in. or 6in. deep. The shelves overrun 7in., 9in. and 11in., spaced about 11in. apart, the top shelf running all round over the top of door and window. Glazed sliding doors in front of the shelves will keep the china and glass clean, especially that which is not in continual use, while brackets of angle iron to support the shelves will be found less clumsy than in wood. They will, moreover, not be in the way when the china, &c., is moved along the shelf. To economise space the pantry may very well be a passage-room between kitchens and hall; in fact, if it is increased in size and has a fireplace, it may also be used as a servants' sitting-room.

Many people prefer the scullery to be the working kitchen and the kitchen proper to become the servants' sitting-room; this is a useful arrangement in a small as well as in a larger house, as in the smaller the same room can be used for breakfast—an advantage where only one servant is kept and the sitting-rooms are not dusted until later on in the morning. The rule that says a kitchen should be as big as the dining-room applies to a larger as well as to a small house, because the larger the dining-room the more people there may be to cook for. One cannot do very much in the way of outside premises, so luxuriously provided for in old houses. Coals, ashes, &c., knives and boots, with perhaps a shed, is all we can expect, but even these should be in a separate yard, not approached by the tradesmen's entrance, and must be also cut off from the stable yard, where there is one.

Buff-coloured tiles, perhaps, look the cleanest for kitchen floors and larders, but are somewhat softer than the red. Ruabon wire-cut 6in. by 3in. tiles last and look well for entrance passages and floors of ingle nooks, but for the latter I prefer stone paving, raised up 3in. or 4in. above the floor of the room. In the Cotswold Hills the ordinary stone from the hard bed is used for paving, and is of a very pleasing colour. Wood-block floors are too expensive to use, except, perhaps, in a billiard room, where the table gets a good foundation from the concrete bed.

Panelling and fittings are almost out of the question for houses of this type, not to mention ornamental plastering; necessities for comfort must not be sacrificed for them, as they can be inserted afterwards.

As to plastering, it is better to carry it round the jambs up to the windows instead of using wood linings and mouldings, which only get covered up with curtains, but as such jambs are liable to injury from staybars, &c., they are better if finished in cement. No mouldings are required. Modelled plaster ought to be kept soft and somewhat indistinct, and quite different from carved stone or wood. For panelling, one must study the old examples to get into the way of treating it properly; both for the small and large panel types you will find how necessary it is to keep the panels exactly the same width, while a gradual and almost imperceptible diminishing in height is desirable as you rise up the wall in the small panel work.

With regard to decoration I cannot say very much. Unless you are very fond of colour and know how to treat it, you will be landed into difficulties, while the selection of wall-papers for clients is conducive to more ructions than anything else. For my own part, the whitewash brush is, I think, a handy instrument, and white paint is very easily mixed.

Concerning the external appearance, we must again turn to our grammar of old examples. It does not follow that because something looks well in an old building it will look well if introduced straight away into a new one, the glamour of age will be wanting, the scale will probably be different, and the surroundings of totally different character; but the close and measured study of old work is, without doubt, an essential part of our education, guiding our minds to value certain ranges of proportion and teaching us the value of surface.

I suppose at one time or another every one does a half-timber house, and wishes they had not after a later inspection. There will be a day of reckoning hereafter when the dilapidations are taken on these top coats of deal boards. It is a great thing in the exterior work to introduce as little as possible that will be required to be renewed and regularly painted. Five pounds a year for the jobbing builder does not seem much, but represents interest on £100; this would probably pay the difference in cost of oak or stone over deal and cover a good deal of that care in workmanship that is so wanting at the present day. Houses built of brick entirely look better in the work than on the drawings, especially in a neighbourhood where good bricks are obtainable; while, if the bricks are bad, whitewash them, either with or without rough cast. This particular treatment is being taken up a good deal now, I suppose as a reaction from the scarlet fever we have been suffering from for some time past. Rough cast certainly has a texture and surface more nearly approaching stonework than anything else, but unfortunately it has a habit of peeling off and wants to be fairly well done.

I do not think it is possible to lay down any rules for designing a satisfactory elevation; it is very much a question of setting out and of the proportion of the solids to the voids, an outcome of the surface and colour of the materials employed, and of the grouping of the blocks of the plan and their roofing. I think one may take it that the solids diminish and the voids increase in the work, and you need not put in what you can possibly leave out. I am afraid this will be thought a very dry and uninteresting discourse on construction, but architecture is nothing but construction, with the addition of a refining and beautifying element obtained by continued and enthusiastic study, developing a certain natural aptitude. I hope, therefore, I shall be forgiven if I have said nothing fresh or very helpful about designing small houses.

A letter from Mr. Ernest Newton was then read. He says: Mr. Bateman strikes a true note when insisting upon the recognition of the practical side of house-building. The proper solution of these problems takes us a long way on the road to the production of a good house; but it is one note only. All these practical requirements may be satisfied and yet the result may be an uninteresting building, devoid of character and quality. Practical problems may be solved in many ways, all right in varying degrees; but to

solve them completely I think two senses must be at work, one definite and teachable, the other the property of the individual. It is not enough to give a practical and obvious solution only; every material we use in building has an expression proper to itself alone; it is not easy to define this, but we feel intuitively that stone and wood must be treated differently, one kind of stone differently from another; lead, copper, iron, all have their fields and their limitations; deal must be treated in one way, oak in another and so on, all through the whole range of materials. The right selection and proper expressive use of materials play an important part in fixing the general character very considerably. Then besides all this sub-expression, the building must have a note of its own, grave, gay, dignified, homely, austere, whatever it is that we are aiming to express. Locality often to some extent determines this character. The conditions may be varied. Three sitting-rooms, a hall, six or seven bedrooms, cupboards, conveniences of all sorts, sanitation, ventilation, all the things so wisely and rightly insisted upon, but if we take house building exclusively from the practical point of view we may get a "dwelling," but not a home.

Half-timber has led us all astray at one time or another, but its inherent falseness for modern use is fortunately killing it. Solidity and plenty of wall space are always right; not only do we want substantial walls, but substantial doors and windows and strong solid floors; flimsiness in a house destroys the self-respect of its possessor, and, in course of time, would be an excuse for almost any crime he may commit. The simple roof is undoubtedly the form most suitable to our climate, and the most restful to the eye. Good tiles ought not to be difficult to get; thick, strong deep red, hand-made tiles, however, are scarcely to be found; tile makers are too much in love with a thing like a piece of boiler-plate painted pink. I believe that if architects were more persistent the demand would create the supply. As it is with tiles, so it is with almost all other materials. The manufacturer's ideal is a hard, highly finished article; finish, rightly applied, has its own beauty and its own place, but its application should not be universal.

In conclusion, I should like to say that what I have endeavoured to make clear is that a house that is the outcome of an honest attempt to grapple with all the practical difficulties is always respectable, and sometimes even interesting, and that the ideal house must have all these qualities, plus a flavour and distinction of its own. The draughtsman's house, like a piece of petrified sketch-book, is a thing without soul or body, and is always ridiculous, uninteresting and impossible.

Mr. Arnold Mitchell proposed a vote of thanks to Mr. Bateman, which was seconded by Mr. Beresford Pite, and supported by Messrs. H. W. Pratt, C. H. Brodie, Arthur Bolton, L. C. Riddett, W. E. Hewitt, A. S. Taylor, H. J. Leaning, E. Greenop, and G. H. Fellowes Prynne. The motion was carried by acclamation, and Mr. C. E. Bateman briefly replied.

Improvements at St. Anne's, Blackpool.—Application is to be made to the Public Works Loan Commissioners for £29,589 for the following purposes:—Electric lighting, £18,161; fire-station, slaughter-houses, and depot, £5,830; street improvements, £4,679; sewerage, £309; mortuary, £170; steam fire-engine, £350.

Leeds and Yorkshire Architectural Society.—The officers nominated in connection with the coming session of the Leeds and Yorkshire Architectural Society are: President, Mr. W. Carby Hall; vice-presidents, Mr. W. H. Beevers and Mr. C. B. Howdill; hon. treasurer, Mr. W. H. Thorp; hon. librarian, Mr. W. H. Beevers; hon. secretary, Mr. F. W. Bedford; council, Messrs. G. Atkinson, W. S. Braithwaite, T. B. Wilson, G. F. Bowman, A. R. Hill (Bradford), and R. Ward; auditors, Messrs. F. Musto and H. Ambler. These names will come up for confirmation at the next general meeting on March 19th.

Engineering Notes.

Electric Light and Trams for Devonport.—Devonport Electric Lighting Committee has approved plans, estimates, and specifications for the erection and equipment of the power station at Newport Quay, and for mains and works in Devonport and Stonehouse. It also recommends the Borough Council to apply to the Local Government Board for sanction to borrow £74,536 to carry out the work.

Closing Breaches in Embankments.—At a meeting of the Society of Engineers on March 5th a paper was read on "The Closing of Breaches in Sea and River Embankments" by Mr. Richard F. Grantham, M.I.C.E., F.G.S., in the course of which he suggested that in the case of land having only an agricultural value, where the area was not too large, the inset wall was the cheapest, and was attended with the least risk.

London County Council Tramways.—The Highways Committee of the London County Council report that, in regard to the tramways owned and worked by the Council south of the Thames, the estimated surplus of receipts over expenditure for the year 1900-1901 is £40,000, and this with sums derived from other sources, including a saving in the estimated cost of repairs during the past year, will leave a total sum of £53,000 available for the relief of rates or for such other purposes as the Council may decide.

New Works for the Metropolitan Electric Supply Corporation have been erected about a mile from Willesden Junction, N.W. The site is about eight acres and a half in extent. When finished, the works will cover over two and a half acres, and will consist of two parallel boiler houses, each 384ft. long by 88ft. wide, with a two-bay engine house between, measuring 384ft. by 112ft., and four huge chimney shafts. This engine house will contain eighteen alternators, capable of lighting about 810,000 eight candle-power lamps. The boiler house as it now stands measures 164ft. by 88ft.

The late Professor David Edward Hughes, a past president of the Institute of Civil Engineers, bequeathed in his will between £300,000 and £400,000 to the Middlesex, London, King's College and Charing Cross Hospitals. Among other public bequests are: £2,000 to the Institute of Electrical Engineers for a "David Hughes Scholarship Fund"; £2,000 to the Société Internationale des Electriciens in Paris for a similar fund; £4,000 to the Royal Society, to apply the income for original discoveries in physical science; £4,000 for like purposes to the Academie des Sciences de l'Institut, Paris; and £1,000 to the Royal Institution of Great Britain, Albemarle Street.

The Suez Canal Works.—At the meeting of the Institution of Civil Engineers on March 6th "A Short History of the Engineering Works of the Suez Canal" was given by Sir Charles A. Hartley, K.C.M.G., M.Inst.C.E. After referring to Sir William Denison's paper of 1867, and giving a general account of the inception and progress of the canal works down to the time of the opening in November, 1869, the author proceeded to describe the new development which had been rendered necessary by the great increase of traffic since 1872. After a great deal of investigation the International Consultative Commission met in Paris in 1885 and accepted the recommendations of the Consultative Commission, which were to the general effect that the canal should be enlarged to 246ft. in straight reaches, and to 262ft. (at the apex) in curves. It was recommended that the canal should ultimately be deepened to 9 metres (29ft. 6in.), but that at first only 8½ metres should be provided. The enlargement works were at once put in hand on this basis, the first stage (to 121ft. 4in. bottom-width, and 8ft. 6in. depth) being completed in December, 1898, twelve years from the commencement of the work.

New Infirmary, Bethnal Green.

THE new infirmary which has been erected in Cambridge Road, E., for the Bethnal Green Guardians (opened last week) has been designed by Messrs. Giles, Gough and Trollope, architects, of 28, Craven Street, W.C., for the accommodation of 750 patients, together with the whole of the staff necessary for the working of the institution. The site has a length of 740ft., with a frontage to Cambridge Road of 330ft. and of 280ft. to Russia Lane, with an area of about $4\frac{1}{2}$ acres. The Cambridge Road frontage is partly occupied by an entrance block, containing, on the ground floor, a commodious committee room, with clerk's office adjoining, waiting room, porter's office, and retiring rooms. On the first floor are suites of apartments for the steward and engineer. The infirmary is planned with a central administrative block, situated midway between the Cambridge Road and Russia Lane boundaries of the site, containing the medical officer's, matron's, nurses', and female servants' quarters, and the main kitchen and stores departments. This block is of four storeys with basement, the latter containing spacious storage for coal, firewood and heavy goods, and having cart access by means of an inclined roadway leading from the main approach road. Lifts to the ground floor are provided for goods and coal. The ground floor contains an entrance hall, medical officer's residence and office, dispensary and assistant medical officer's common room, chaplain's office, matron's sitting room, nurses' messroom and recreation room. Separating the front portion of the block from the back is the main corridor running east and west to the wards, enlarged at its centre to form a serving hall. Opening from the serving hall is the main kitchen, around which are the scullery, vegetable scullery, larder, dairy, pantry, &c. Supplies are brought up to this department by a lift from the stores below and all refuse passes down glazed shoots into portable receivers in the low level yard at the back, and is thence carted away. To the east of the main kitchen, &c., is the stores department; on the west is a department under the direct control of the matron, comprising servants' hall, with scullery attached, matron's office, matron's store, and large sewing room. To the rear of and detached from the matron's department is the steam laundry, a two-storey building. The mortuary is on the same floor as the laundry, and in the basement storey under the latter is the electric light and heating plant. The medical officer's residence has been provided at the north-east angle of the administrative block and incorporated with the main building. A wide staircase leads up from a corridor near the nurses' mess and recreation rooms on the ground floor to the three floors of nurses' bedrooms above. The nurses number eighty, each having a separate bedroom. All w.c.'s have cross-ventilated lobbies. In order to provide for the better circulation of air around the large block of buildings, the continuity of the building has been interrupted at suitable points and the necessary communication obtained by bridges across the spaces thus formed. The wards are contained in separate blocks or pavilions, three on each side of the administrative block, and connected with it and with each other by a corridor on the ground floor only. This corridor is an extension to the east and west of the main corridor, and is 10ft. wide throughout. It has a flat roof which forms a promenade for convalescent patients in fine weather. The receiving rooms for patients (a separate suite being provided for each sex) have direct access to this main corridor. Each consists of a one-storey building. The wards are all of three storeys and extend northwards and southwards of the main corridor. The axis of all the wards is thus north and south, this being the best possible disposition for the reception of sunlight on both sides. They are all arranged on one principle, the majority of them being intended for twenty-eight patients. Each pavilion contains a spacious staircase, a direct-acting hydraulic bed lift, and a food and coal

lift for the service of the upper wards. Each ward is approached from the main corridor or staircase by a short corridor, opening from which are a small ward for two special cases, with separate w.c. accommodation, a ward kitchen or nurses' duty room, a small storeroom for patients' clothes, and another small storeroom for ward linen and requisites. The large wards are 24ft. wide, arranged for the beds in pairs on each side between the windows. Central stoves are used for warming, in addition to which low-pressure hot-water radiators are provided at the sides. All the wards have foul air extraction shafts, and the windows are fitted at the top with ventilating hoppers of special design, and have sliding sashes with wide guard heads at the bottom for allowing ventilation at the meeting rails without draught. Tobin ventilation shafts are also provided. Two sanitary annexes or towers are provided at the ends of each ward, approached through cross-ventilated lobbies, and between them is a balcony for the use of convalescent patients. Iron fire escape staircases are provided at the ends of wards furthest from the main staircase. Isolation wards are provided in three three-storey pavilions. These are aerially isolated from the main buildings, the only connection being by a covered way or bridge open to the air on each side. The wards are for ten beds each and are similar to the general wards, except that a larger proportion of space is provided per bed. The buildings are erected of stock bricks with best quality facings, relieved by strings of moulded white Suffolk bricks. The heads and sills of windows, plinths, &c., are of Portland stone. Internally the walls of corridors, kitchens, sanitary annexes, &c., are faced with tinted glazed bricks to dado height. The wards have Keen's cement dados, all angles being rounded. The main corridors and other parts have marble mosaic paving, and granolithic paving is used in the administrative block. The floors of the wards generally are of pitch pine, polished. Mr. Thomas Rowbotham, of Birmingham, was the general contractor. The electric lighting has been carried out by Messrs. Calvert and Co., of Manchester. The total cost of the building was £200,000.

PORTLAND CEMENT:*

Its Origin, Manufacture, and Testing.

By W. G. DAY.

THE somewhat misleading name of "Portland Cement" was given to the artificial compound of lime and clay prepared by Mr. Joseph Aspdin, a Leeds bricklayer, in October, 1824, which was exhibited at the Industrial Exhibition of 1851. He chose this name in consequence of its fancied resemblance in point of colour and texture to the oolitic limestone of the island of Portland, well known and in great favour in this country as a building stone. In the year 1825 Mr. Aspdin erected a works at Wakefield, and for him may be claimed the honour of having manufactured and supplied the Portland cement used in the Thames Tunnel about 1828. Although at that time it cost 20s. to 22s. per cask, besides the cost of carriage from Wakefield to London, Sir I. Brunel decided (notwithstanding his ability to procure Roman cement at 12s. per cask delivered on the spot) to use Portland chiefly for his purpose, as its merits required no other recommendation than an impartial trial. There is no doubt that the Thames Tunnel was the first engineering work of importance in which Portland cement was used, as in its earlier days it was mainly a stucco cement, and it was not until very much later that it acquired the confidence of the engineering profession. One of the founders of the Portland cement we use to-day was the late Mr. I. C. Johnson, who, having improved on the quality of the cement manufactured by

Aspdin, established the first factory on the Medway at Frindsbury, near Rochester. Before the success of Aspdin's material was thoroughly assured, Johnson launched out by renting several acres of land near Gravesend, and commenced building Portland Hall in such an elaborate and artistic manner as to require some £40,000 to bring it to completion. When the structure was rather more than one-third completed he had to stop, and sold off at so great a sacrifice that he left the country and died abroad. The banks of the river Medway above Rochester Bridge possess special advantages for the erection of cement works, as a very short distance inland an abundant supply of chalk can be obtained at a nominal cost, in addition to which the clay used in the manufacture is obtained from marsh land on each side of the river. The cost of the original ingredients being minimised in this way is the principal reason why Portland cement can be sold at such a comparatively low figure. While to many of you its price may appear very high, I think, as we proceed with the process of manufacture, you will be convinced of the truth of my claim as to the small cost of an article which is daily proving its superiority over many of its substitutes, not only from an economical point of view but also in its durability, and from the fact that to-day the manufacture of Portland cement has reached that stage of perfection when manufacturers can justly claim to be able to produce it to meet the requirements of many classes of work never before contemplated. As many of you no doubt are aware, some of the firms now supplying cement for building purposes in London and the provinces also supply cement for all classes of work in Egypt, South America and South Africa, where the climate puts a far greater strain upon its durability than in our own country. Before proceeding with the process of manufacture, a few figures relating to the raw materials and the extent of the variations in their proportions may be of interest.

White chalk contains from 90 to 100 per cent. of calcium carbonate, while the percentage in grey chalk may be as low as 60, the other constituents being silica, alumina, and iron oxide in varying proportions. The moisture varies from 40 to 50 per cent. Dried clay contains the following:—

	Per Cent.
Organic matter and combined moisture	1 to 10
Silica	50 to 65
Alumina	15 to 23
Iron oxide	5 to 9
Calcium carbonate	0 to 5
Magnesium carbonate	0 to 5
Alkalies	0 to 2

Medway Clay.

A good Medway clay contains at least twice as much silica as alumina and iron oxide combined. A typical analysis is as follows:—

Organic matter and combined moisture	4.77
Silica	59.96
Alumina	16.82
Iron oxide	6.20
Calcium carbonate	5.75
Magnesium carbonate	4.89
Alkalies, &c.	1.61

100.00

PORTLAND CEMENT MANUFACTURE.

Portland cement manufactured on the Thames and the Medway is composed solely of chalk and clay. The clay is brought to the works in barges, deposited in heaps on the wharf, and thence in wheelbarrows to the washmills. The chalk being, as a rule, close to the works, it is filled into trucks at the quarry, and is also conveyed to the washmills. These are circular brick-lined pits, in each of which revolves a spider, the arms of which carry what are very similar in construction to harrows, and as these revolve they strike against the lumps of chalk and break them up. The chalk and clay in given quantities are deposited in the washmills simultaneously, a standard weight of chalk being used, and the proportions of clay are

*A paper read before the College of Masons on February 13th, 1900.

determined by the results of tests made from the mixture. The proportions are, roughly, two thirds of chalk and one of clay. A constant supply of water is maintained, which assists in the intimate mixing of these two substances, and the thick creamy liquid resulting is termed slurry. In one side of the washmill is a grating of iron bars with about $\frac{1}{4}$ in. spaces through which the slurry passes into a catchpit. From this it is elevated by means of an endless chain of buckets into a hopper erected in the grinding mill; small particles of chalk not disintegrated in the washmill require grinding to ensure a perfect mixture, and to avoid what is known as "free lime." The stones used for grinding purposes are formed of "French Burr" and are placed horizontally, the lower one remaining stationary while the upper one revolves at a speed of 120 revolutions per minute. These are fed from the hopper into which the slurry has been elevated. After being ground, the slurry passes into mixers (which consist of circular pits like the washmills, with bars of angle iron attached to a horizontal arm, revolving like the spider in the washmills), and while so doing samples are taken for testing purposes in the following manner:—About one pint of slurry is taken at given intervals, and a portion of it thoroughly dried and reduced to powder in a mortar; then, after cooling, the test for percentage of calcium carbonate is proceeded with. This is determined by means of an apparatus technically termed a calcimeter. If the slurry is found to contain a greater percentage of calcium carbonate than is required, clay in proportion to the excess of chalk is put into the washmills to counteract. If, on the contrary, the percentage is too low, the quantity of clay is reduced proportionately, and a further test for calcium carbonate is made to ensure that the alteration in the proportion of clay has had the desired effect. The balance of the pint of slurry taken is now placed in a sieve (having 5,776 meshes to the square inch) which is held under a water-tap until all that can have passed through, the object of this test being to ascertain if the chalk has been efficiently ground.

Another test, of greater importance to-day than ever in the past, is that made for the percentage of water in the slurry, which varies between 40 and 45 per cent. Owing to the dearth of coke during the summer months, many firms are compelled to close a portion of their works at this season. Taking advantage of this, the gas companies have now increased their prices to such an extent that cement manufacturers are threatened with greater difficulties than ever in manufacturing cement at a cost which will enable them to sell at a profit; and I have no hesitation in saying that, as a result, the imports from Germany and Belgium will be largely increased, as English manufacturers cannot possibly continue to sell at present prices.

The slurry in the mixers is now ready for drying, and is pumped into the chamber or drying floor to a depth of 9 in. or 1 ft. previous to burning. Both these processes of drying and burning are conducted at one operation in one kiln, the method adopted varying slightly with the different type of kiln. Speaking generally, the kilns consist of two parts, the kiln proper and the chamber or drying floor. The kilns have a perforated brick bottom, and in starting to load them about twenty faggots (according to the size of the kilns) are placed on the bottoms; upon these, coke of a large size is placed to ensure a good heat in commencing the burning process, the remainder of the kiln being filled with alternate layers of dried slurry and coke. The success of the burning process depends to a very great extent on the skill of the man who regulates the proportions of coke and dried slurry in the various layers of the kiln. The filling of the kiln being completed, the chamber or drying floor is now filled with the liquid slurry. The kiln is lighted from the bottom, the fire gradually working its way through the contents. At the same time the hot gases from the combustion passing over the liquid slurry in the chamber dry it in readiness for the next filling of the kiln. Here is seen the importance

of keeping the percentage of water in the slurry as low as possible, as, if an excess is used, additional fuel has to be put into the kiln to render the slurry dry enough for the next filling. The average time occupied in the burning process is five days, and at the end of this period the ashes are cleared from the bottom and the contents of the kiln loaded into trucks and taken to the mills. The well-burned clinker is black in colour, with a greenish tint, but there is always present in the kiln a small proportion of underburned clinker, which varies in colour, and may be white, yellow, or pink. As the presence of this underburned material is detrimental to the quality of the cement, it is the aim of the burner to load his kiln in such a way that a minimum of it is produced, and great precautions have to be taken that none of it passes to the mills with the well-burned clinker.

The output of each kiln varies from twenty to thirty tons. For a works producing 1,000 tons per week, about forty kilns would be required, as a considerable allowance has to be made for kilns under repair. The clinker is first broken in crushers of the usual stone-crusher type and then passes to the mills to be ground to the required fineness. These mills are of three principal types, of which there are almost innumerable modifications. The first and oldest type is the bed stone and runner, similar to those used in flour milling. These, although giving a splendid product, are too expensive to be largely used owing to the enormous power required to drive them. The next is the edge-runner type, which is very extensively used at the present time under the designation of Collis-Freeman Mills, Dutrulle and Solomon Mills, Neate's Dynamic Grinder, Taylor and Duffield Mills, and others. Although these mills do their work at comparatively small cost, the product contains a much smaller proportion of that "flour" which goes to produce a well-finished cement. The third and most recent type is that known as the ball mill, which consists of a revolving steel cylinder containing heavy steel balls. The crushed clinker is fed in at one end and, passing along the cylinder, is ground by the action of these balls. As a rule, in connection with all these types of mills, there is a system of sieves or separators into which the ground cement passes in order to eliminate any particles of clinker which exceed the required fineness. From the mills the finished cement is conveyed by means of Archimedean screws to the various stores or warehouses.

Testing.

The tests which are usually made in accordance with the requirements of the more important specifications are the following:—(1) Weight per bushel or cubic foot; (2) specific gravity; (3) fineness of grinding; (4) setting time; (5) tensile strain; (6) soundness; and (7) chemical analysis.

(1) *Weight per Bushel or Cubic Foot.*—The origin of this test belongs to an early period when cement was sold by the bushel, and naturally the purchaser preferred a cement which gave a heavy weight per bushel. The real value of the test is in determining whether the cement has been thoroughly burned, as the presence of even a small proportion of underburned clinker causes a considerable decrease in the weight. It should be remembered, however, that the fineness of the cement has a great influence on the weight per bushel. It has been found by experiment that a cement ground to a fineness of 5 per cent. on a sieve of 2,500 meshes to the square inch gives an average weight of 116 lbs. per bushel, while the same cement ground to such a fineness as to leave no residue on a 50 mesh sieve has an average weight of 111 lbs.; hence, in specifying that a cement should have a given weight per bushel, the fineness should always be taken into account. In many recent instances the weight per cubic foot has taken the place of the weight per bushel; this varies from 85 lbs. to 90 lbs. A fairer criterion of the thoroughness of the burning is undoubtedly obtained by the specific gravity test.

(2) *Specific Gravity.*—The specific gravity of a well-burned cement, when freshly ground,

varies between 3.12 and 3.16, but a cement that has been aerated to any extent may be taken as satisfactory if the specific gravity exceeds 3.05.

(3) *Fineness.*—A great revolution has taken place in recent years with reference to the requirements for fineness; only a short time ago a cement leaving a residue of 15 to 20 per cent. on a 50 by 50 mesh sieve was considered fine, whereas now the extreme limit is 10 per cent. on a 50 by 50 sieve, and occasionally cement is required to be ground so fine as to leave no residue on a 100 by 100 mesh sieve (10,000 meshes to the square inch). In dealing with the question of fineness, there can of course be no doubt that a finely ground cement goes farther when used for concrete, and develops its maximum strength at an early date, but the ultimate strength attained by a fine cement does not exceed that attained by the same cement coarsely ground. Taking into consideration the increased cost of fine grinding, a cement which has a residue not exceeding 5 per cent. on a 50 by 50 mesh sieve seems to be the most suitable for general purposes.

(4) *Setting Time.*—It is of great importance that those using cement should know its setting time, as concrete or grout which is disturbed after the setting has commenced loses much of its strength. The setting time is usually determined by gauging the cement with a minimum quantity of water and noting the time which elapses when it is impossible to make any impression with a Vicat needle on the surface of the cement.

(5) *Tensile Strain.*—The tensile strain of Portland cement is usually looked upon as its most important characteristic and is an almost universal test. The usual method of procedure is to fill the cement, gauged with a minimum quantity of water (about 20 per cent.), into moulds of 1 in. by 1 in. section. After remaining in these moulds for twenty-four hours the briquettes are placed in water for three, seven, fourteen, twenty-eight days, or even longer periods. They are then tested in machines of varying types, with which no doubt you are quite familiar. The period usually specified at which the tensile strain is to be determined is seven days, the average strain, and one which I consider quite reasonable, being 400 lbs. Many specifications require that briquettes made of 1 part cement mixed with 3 parts of standard sand shall produce certain strains at seven and twenty-eight days, the most usual being 100 lbs. at seven days and 200 lbs. at twenty-eight days. Although the sand tests are regarded as of little importance in comparison with the neat, yet it should be borne in mind that cement is almost universally used with sand, and consequently the neat tests may be misleading, and in this particular the German engineers are teaching us a lesson, the criterion in that country as to the value of a cement being obtained almost exclusively from the sand tests.

(6) *Soundness.*—A simple test for soundness is to gauge a small quantity of cement and place it on a piece of plate glass or slate in the form of a thin cake or slab. This is immersed in water after it is set, and if at the end of seven days no cracks are visible on the surface or the cake has not buckled, the cement is regarded as perfectly sound. Some specifications require the cake to be immersed in water immediately after gauging; but experiments have proved that this test is not a fair one for soundness, the freedom from cracking depending to a very large extent on the setting time and the temperature of the water in which the cake is immersed. Other specifications require that the cake should be immersed in hot water for a period of twenty-four hours without showing any signs of disintegration.

(7) *Chemical Analysis.*—Chemical analysis is a test which is somewhat unnecessary if the cement has satisfied all the above-mentioned requirements, and it is only for the more important contracts and in cases where the cement has proved unsatisfactory that it is usually applied. It is somewhat difficult to draw any hard and fast line limiting the proportions of the various constituents. The following may be useful as showing the varia-

tions in the parts per cent. of the various constituents usually present in Portland cement:—

	Per Cent.
Insoluble matter	0.5 to 1.5
Silica	20 to 23
Alumina	7.5 to 11
Iron oxide	2 to 4
Lime	59 to 64
Magnesia	1 to 1.5
Sulphuric anhydride	0.5 to 2
Alkalies	1

A typical analysis of cement is as follows:—

	Per Cent.
Insoluble matter	1.12
Silica	22.14
Alumina	8.38
Iron oxide	3.30
Lime	62.26
Magnesia	1.24
Sulphuric anhydride	1.39
Alkalies, &c.	0.17
	100.00

Under Discussion.

Damascus.

A lecture on "Damascus, the Immortal," was delivered by the Rev. E. H. Smith before the Hull Literary and Philosophical Society on March 6th. It was, he said, the oldest city in the world, and was undoubtedly the only city that had maintained unimpaired continuity from the days when it was first founded. Abraham lived four thousand years ago, and they read that Abraham's servant was a native of Damascus, and that Abraham himself passed through the city on his way to the land of Canaan; and it was very probable that the Patriarch saw the very same street scenes and customs which were to be witnessed at the present day. The word Damascus meant "renowned for activity." With the aid of a number of photographs taken by the lecturer and thrown on a large screen, the audience were able to follow the speaker on a tour round the city. He exhibited the mosque built by Arcadius, son of Theodosius, fifteen hundred years ago, of which unfortunately was burnt and totally destroyed on the 14th of October, 1893. A bird's eye view of Damascus was given, which showed the street called "Straight" mentioned in the Acts of the Apostles. All that remained of it at the present time was one of the side footpaths, the main roadway and the opposite footpath having disappeared.

The Comacine Builders.

Mr. Thomas Drew, R.H.A., vice-president, read a paper on "The Comacine Masters in Ireland" before the Architectural Association of Ireland, on March 6th at Dublin. Mr. Drew said that very many pedantic theories were being dissolved by modern travel and the improvement of photography. People believed in these days of tourists' guide books and excursions that those who lived in the early ages did not travel, but the contrary was the case. Though progress was slow, it was none the less continual. Soldiers of fortune, crusaders, clerics, and, as they now knew, builders passed from land to land; and the language of medieval Europe was more of an approach to universality than the language of our own more educated day. He referred to the influence which the migratory associated bands of master builders exercised on architecture in explanation of the Comacine symbolism. Dealing with early church architecture in Ireland, he expressed the opinion that it had its origin in the teaching of the Comacine Masters. A noble architecture had its birth, its rude, and masculine beginning around Como first; and then developed the strange, symbolic and mystic sculpture of the Comacines that might be traced in all lands—in Sicily, southern and western France, and to England and remoter Ireland. He referred to the incased stone now in the restored chapel of St. Laurence O'Toole, Christ Church, Dublin, relating to "John, the Master

Builder (Lombard), son of Raymond of Parma, and Dame Rame Perez of Saint Salvador of Asturias," and he belived this record of a Comacine Master Architect Freemason in Ireland in the twelfth century was unique in England, Ireland, and Scotland. He pointed out that "John, Master Builder, from Asturias," had built additions to Christ Church, as it had been originally built by Sitric, the Danish King.

Welby Pugin.

Mr. Peter Paul Pugin read a paper on "The Work of the late Welby Pugin" before the architectural section of the Glasgow Philosophical Society on March 5th. He said that who was the art architect of the Houses of Parliament had always been a bone of contention between the families of the Pugins and the Barrys. A great controversy on the subject took place in 1863, and he, as the son of Augustus Welby Pugin, had no hesitation in saying that he considered his father was the art architect of the Houses of Parliament. One had only to look at the building to see the great impress of his genius everywhere. Amongst 84 sets of drawings that were sent in for the competition of the Houses of Parliament, Pugin made designs both for Sir Charles Barry and Gillespie Graham. Barry was a classic architect, and made a classic plan, and from it Pugin raised the Gothic elevations. With Gillespie Graham's drawings he had a far freer hand. Gillespie Graham had given a plan in the genuine spirit of Gothic architecture, defying symmetry and order, but presenting combinations of convenience and picturesque grouping in perfect keeping with the character of the style and most delightful to contemplate. Pugin never at any period of his life sought to associate himself with any institution or chartered body having for its object the promotion of arts, yet he never withdrew himself from his professional brethren, and was always ready to give assistance or advice when asked. Pugin built more than sixty-five churches in the United Kingdom and many in the Colonies, besides convents, monasteries, mansions, and schools, and made endless designs for works which were executed, the authorship of which he never claimed. He had not yet arrived at the meridian of his power when he was taken down to the silent grave. Pugin's tomb was in no place of public honour. No reward fell to his lot, living or dead.

Scotch Ecclesiastical Architecture.

On page 79 of last week's issue we gave a report of Mr. Thomas Ross's first lecture on "Ecclesiastical Architecture in Scotland from the Twelfth to the Sixteenth Century," delivered at Edinburgh. In his second lecture he completed the list of places in Scotland with parish churches that still retained remnants of Norman architecture, but added that it was only by including the Norman remains to be found in the great abbey and cathedral churches, and the references in abbey rolls and charters to churches no longer existing, that one obtained a true idea of the great building activity of the twelfth century. After examining the plan of the various cathedral and abbey churches, Mr. Ross commented, in his concluding remarks, on the preference displayed in Scotland for the square rather than the apsidal form and east end throughout the twelfth century. At the commencement of the third lecture he said they had now arrived at a period when the architects of the Middle Ages had mastered the principles of stone vaulting in an entirely new and logical manner, so much so that were every Gothic building to be swept away with all the representations of them the style could probably be invented again. For that, however, it would be necessary to recall the old state of society. Although Scotland could not pretend to have done much to bring about the creation of the style, buildings of great beauty and interest were erected in great numbers, of which only a mere handful remained, and not one of them anything like a complete building. Of all the cathedrals, Glasgow, it was often said, was the only one left entire.

But was it entire or anything like entire? Where were its western towers, one of them a fine castellated keep? Where was the Bishop's Palace, which was as large a structure as the cathedral itself? Where were all the carved woodwork, monuments, illuminated books, metal work, jewels and vestments, paintings and sculptures? Yet this was the most complete and best example we had—an empty shell. Mr. Ross afterwards passed in review the cathedral churches of St. Andrews, Elgin, and other great Gothic structures. In his fourth lecture he continued his description of the great Gothic structures, dealing with the abbeys of Lindores, Inchcolm (in many respects the best preserved abbey in Scotland), Culross, and Cambuskenneth. Continuing, the lecturer referred to the check which progress in Scotland received consequent on the death of Alexander the Third in 1286. Although but few ecclesiastical buildings were erected during this period, there was considerable employment for masons in the building of castles and in the enlarging and strengthening of those already existing; and especially towards the close of the fourteenth century, and after, the number of castles on hand was very great. The erection of these stubborn castles had a most important effect on the later Gothic architecture of Scotland. When churches again began to be built in Scotland in considerable numbers this long apprenticeship to castle-building had so completely changed their ideas of architecture that we constantly saw reminiscences of the castles appearing in the churches. And as time went on this tendency increased more and more. It was somewhat curious that there should then have been built the church which illustrates the principles of Gothic construction better, perhaps, than any other building in Scotland. We had hardly any building which contained such fine work as Melrose, and in such fine profusion. There must have been a race of artificers here such as had not been seen since in Scotland. And they had been fortunate in having found a stone to work with, which, both in appearance and in enduring quality, left nothing to be desired. They had been most unfortunate that not one-half of their work remained, and the country had lost in reputation from the ruin of a building which was evidently a masterpiece of architecture.

Masters and Men.

The Airdrie and Coathridge Joiners are out on Strike against a reduction in wages of a ½d. per hour.

Plasterers Dispute.—About 300 plasterers came out on strike last week in London in opposition to a rule providing that an independent arbitrator might award damages against either masters or men in case of a breach of the rules.

Perth Station Painters' Dispute.—Some time ago a dispute arose among the men employed in repainting Perth Station regarding their wages. The Glasgow men it seems are paid at the rate of 10d. per hour, according to the rules of their Association. The Perth men, on the other hand, only receive 9d. per hour, and among them an agitation arose with a view to their being placed on an equal footing with their Glasgow colleagues. The men employed within the city of Glasgow were paid at the rate of 8d. per hour, while the men sent to work outside required to be paid at the rate of 10d. per hour. The men are of the opinion that the masters are bound to abide by that agreement. Having failed to come to a settlement the men came out on strike last week, and, according to the rules of the Association, the Glasgow men also stopped work. About fifty Perth men are on strike.

A Memorial Window in St. Bartholomew's Church, Bristol, has been erected by Messrs. Joseph Bell and Son, of 12, College Green, Bristol.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"Wherefore I perceive there is nothing better than that a man should rejoice in his own works, for that is his portion."—ECCLESIASTES.

Our Inset Plates.

IN the report of last Friday's meeting of the Architectural Association, particulars are given of Mr. Bateman's designs for small houses. The houses at Willenhall Park, Barnet, are a fair example of the class and character of the residences now in course of erection on this estate. Special care has been taken by the architect (Mr. G. D. Martin, 3, Pall Mall East, S.W.) in the design and planning of each individual house to take full advantage of the contour of the site and the position, shape, and size of the plot on which it is to be built. The materials for the large house are red brick facings for the ground floor walls, while the first floor is treated with half-timber work and tile hangings. The principal external features of the design are the angle bay window in the drawing-room and the large window over the entrance porch, which lights the main staircase and central hall. The former is decorated with a deep frieze of ornamental cast-lead work between the windows of the ground and first floor. The roof is covered with red tiles, and the external wood of sashes and frames, &c., is to be painted white, the casements being filled with plain leadlights. In the smaller house the external walls are rough cast. The scheme for the development of the site includes the erection of a spacious club house with tennis courts and bowling green for the use of residents.

Architects and Illicit Commissions.

THE honorary secretaries of the Birmingham Architectural Association have sent us the following copies of correspondence for which they desire publicity. The first letter is addressed to Mr. W. H. Bidlake, president of the association, by Mr. George Kenwick (Birmingham), who says: "It is notorious that Fellows of the Royal Institute and other practising architects do accept illicit commissions, if it is possible to find the meaning of these terms. I give the following examples: (a) Only a few weeks ago the representative of a well-known firm of terra-cotta manufacturers offered a client of mine the usual (!) commission for or on the terra-cotta included in the bill of quantities, and amounting to nearly £2,000. The architect refused; the manufacturers' representative was surprised. As this is an instance outside Birmingham it cannot be used as a reflection on this Association. (b) It is well known that provisional amounts are paid by builders to architects who hand over their cheques or cash to the manufacturers. This is done largely in this city. Lastly, I think it would be well if this Association would define the meaning of 'illicit commission,' and state whether it is competent for an architect to receive any other amount than his architectural charges."

The Association's Reply.

IN their reply, the honorary secretaries said: "Your letter of December 5th, addressed to the President of the Birmingham Architectural Association, has been considered by the Council, and we are desired to say (1) that the reference to commission in the circular to which you allude was marked 'private,' and therefore could not be open as you state; that as a member of this Association you must be aware that the receipt of commissions other than those legitimately due from clients is systematically discountenanced not only by this Association, but also by the R.I.B.A. All members of this Association and Fellows and Associates of the Institute have on their election to sign a declaration containing the following words: 'I promise and agree that I will not accept any trade or other discounts, or illicit or surreptitious commissions or allowances in connection with any works

the execution of which I may be engaged to superintend, or with any other professional business which may be entrusted to me.' With regard to that paragraph of your letter marked a, the statement of what a business firm's representative may have said is no proof against architects; but the Council assure you that if you or anyone else can give the precise particulars of any architect having received commission from builders or tradesmen supplying materials used in works carried out under his directions, enquiry will be made and action taken. As to paragraph marked b, the Council have absolutely no knowledge of what is well known and largely done in this city. You, as a quantity surveyor through whose hands a number of builders' accounts probably pass for settlement, will know that it is usual to adjust these provisional sums, and, should the amounts expended be less than the provisions, the balance is credited to the employer without either cheque or cash passing through the hands of the architect. In reply to the question in your last paragraph, the Council consider that illicit commission is clearly defined by the declaration previously referred to, which debars the architect accepting any commission or payment other than his legitimate fees, which are paid by or with the knowledge of his client. We are further desired to forward your letter and this reply for publication in the local and professional papers."

Spurgeon's Tabernacle.

IT is now nearly two years since the Metropolitan Tabernacle was almost entirely destroyed by fire. Soon the re-opening of the new building will take place. It will be remembered that the fire gutted the interior, but left the main walls standing, so that exteriorly the Tabernacle will not be much changed. The back wall has required most reconstruction. But a new wall has been built within the Tabernacle itself, about 13ft. from the original back wall, the space between being occupied by several rooms, including offices for various allied societies. Thus the interior of the building—that is, the main auditorium—will be about 13ft. shorter than it was before. Another alteration is the greater depth of the hall in the basement. The old lecture room and schools, which occupied the basement, were greatly burnt. The ground was dug out 1½ft. lower, so that, although the ceiling—that is, the floor of the Tabernacle above—is at the same level as before, the hall below is more lofty. When the Tabernacle is opened for public worship, this new hall will be divided into lecture hall and schoolrooms as before. The depth being greater, the windows have been carried 2ft. lower, and the reveals are covered with an opalescent substance which reflects brightly, so that the new hall is well lighted. The floor above is of concrete and steel girders, covered with wood blocks of pitch-pine; the gallery floors are also of steel girders and concrete, covered with wood; but, there being no air under the wood, it is rendered almost unflammable, and the floors are regarded as fireproof. No fewer than nine staircases have been built, all except one being constructed of stone and concrete; the exceptional one, which is for the vestries, being of iron. Nearly all the iron columns are new, but some of the old ones were preserved, among them being the smaller columns on which the pulpit of the late Mr. Spurgeon was supported. These will be employed for a similar purpose for the new pulpit. The total cost will be £44,576.

Conway Castle.

ANTIQUARIANS and architects will regret to learn that serious injury has been caused to the venerable and picturesque ruins of Conway Castle by the collapse of one of the two remaining archways in the Banqueting Hall. The recent tempestuous weather is said to have been the immediate cause of the accident; but it may easily appear, on examination, that the ivy growth and the constant vibration of the trains which pass quite close to the ruins, had done much to render it possible (what would Ruskin

have said?). The disappearance of any portion of this peculiarly interesting fortress would have been a calamity; but the Banqueting Hall was a particularly noble apartment, of such great size—it was 130ft. long and 30ft. high—that three fireplaces were needed to warm it, even in the days when the trunk of a small tree was the fitting fuel for a baronial hearth. It is to its bold and commanding position on the estuary of Conway river, even more than to its history, that the Castle owes its fame. Its grim, serrated outlines, seen against an evening sky, are remarkably impressive, and suggest a ponderous strength which has for long past been merely a delusion. Telford's graceful suspension bridge over the estuary was a distinct addition to a beautiful scene, but the tubular railway bridge, constructed by Stephenson, has hopelessly marred effects which were once the delight of every artist and every lover of fine scenery. It seems a great pity that the influences of modern civilization should destroy so quickly that which has withstood so well the ravages of centuries. With reference to the vibration of trains near the Castle, it is stated that one of the towers is in a dangerous condition, and that the railway company gave £50 for its repair some time ago, but that hitherto nothing has been done. A strenuous effort ought really to be made to preserve these interesting ruins.

Finnish Art.

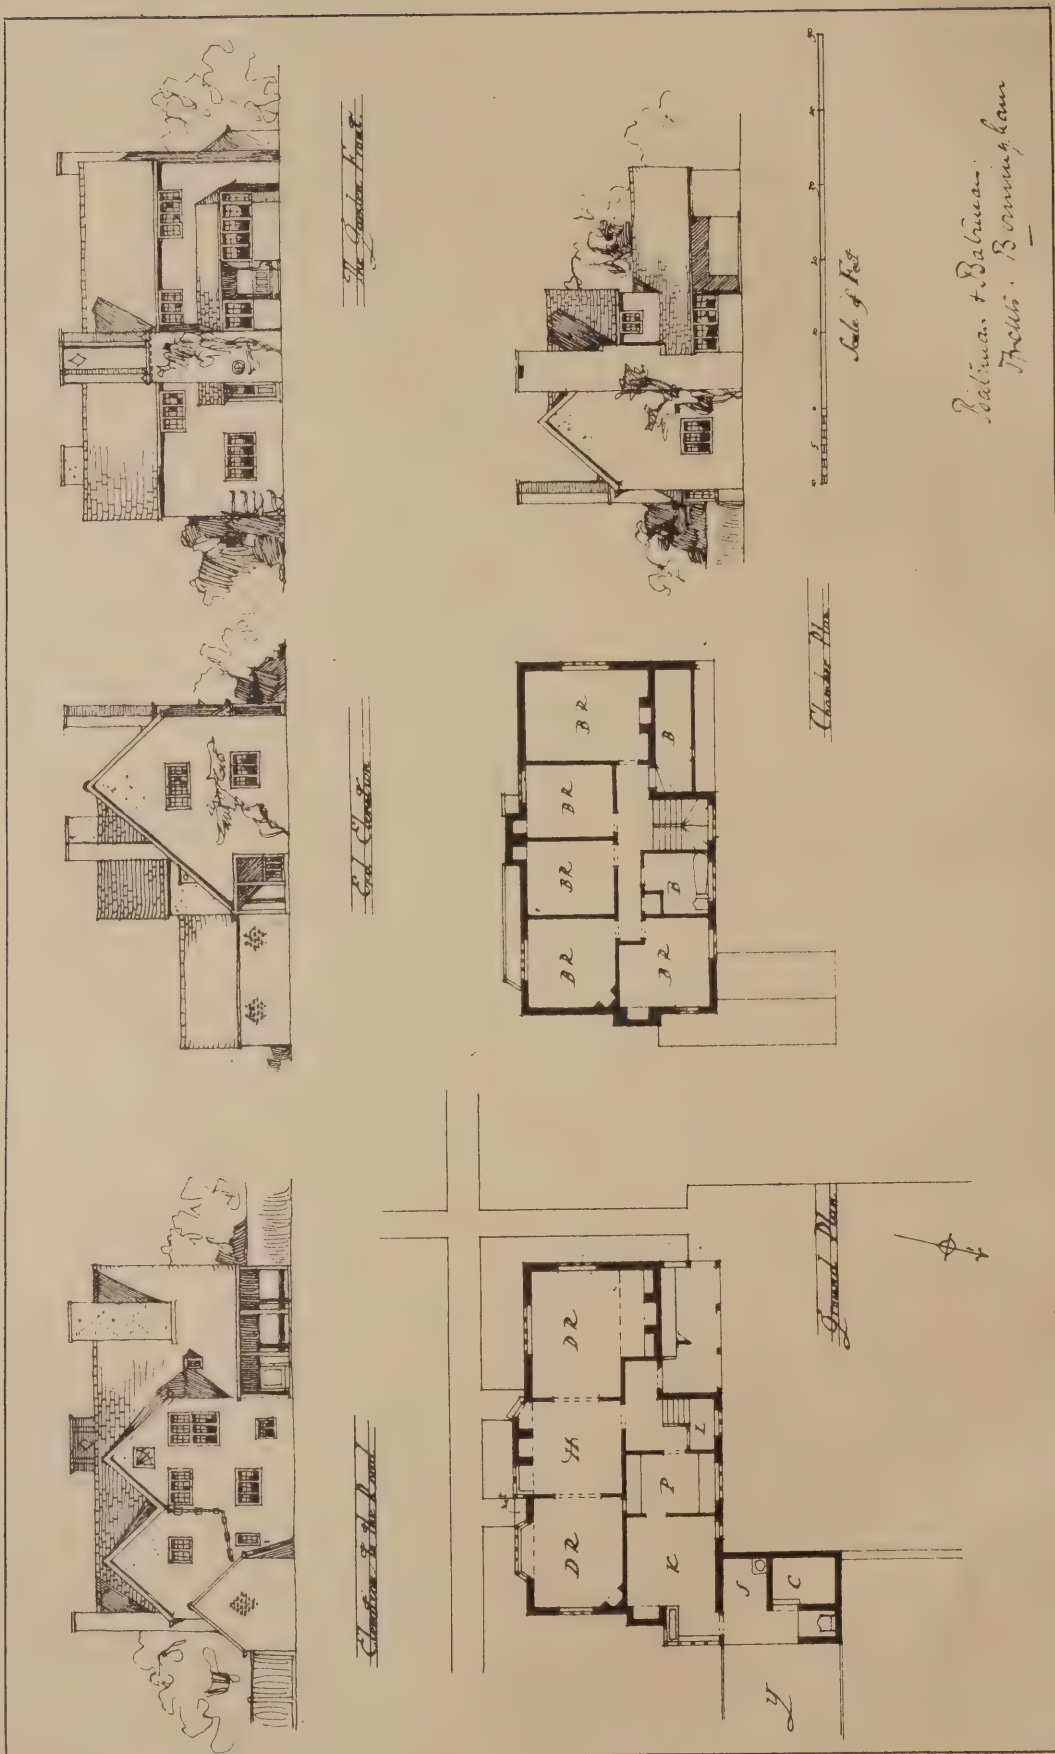

ACCORDING to Emerson, every genuine work of art has as much reason for being as the earth and the sun. In the last number of "Finland" (a monthly magazine) attention is called to the development of art in that country. The old Finnish churches, built of the stone which the glaciers bestowed so bountifully upon Finland, tell us that many hundreds of years ago the country produced architects, who, if not greatly daring in their conceptions of the beautiful, were at any rate thorough and substantial men; while the same religious enthusiasm that inspired Giotto to cause the walls of Florence to live with his frescoes, brought primitive yet wondrous altar pieces and pictures, with painted walls and ceilings, into these lonely temples of the north. The blighting hand of the Reformation was scarcely felt in this direction, and the decorative artists worked steadily down to the end of the eighteenth century. The first great name of a Finnish artist is that of Lauraus, a native of Abo, who, however, deserted his country for fields that offered a wider scope for his ambition. He died at Rome in 1823, and one cannot say that his work had any influence upon the progress of art in Finland. With Robert Wilhelm Ekman, born at Nystad in 1808, it was otherwise. He received his art training in Stockholm, and in 1845 founded in Abo a humble drawing school. In 1846 the Finnish Art Union was founded in Helsingfors. It soon opened a drawing school, and in 1851 took over Ekman's school at Abo. The nucleus of a permanent collection of pictures was formed, and support and encouragement were extended by the Society to all who seemed inclined to follow art as a profession. The Union recognised that "the teaching of art is the teaching of all things," and the State was soon wise enough to realise this truth also, for it began to vote yearly sums for the maintenance of the schools of the Union, and, in and after 1863, for travelling scholarships. Later on came pensions for deserving artists, yearly prize competitions, general exhibitions in Helsingfors, purchases of important pictures, &c. In 1885 the building of the Athenæum was commenced at the expense of the nation, and the completion of the work in 1887 provided a home for all the art societies and industrial art unions of Helsingfors. There are to-day art unions in Abo and Viborg; an Artists' Guild, founded in 1864; and many other artistic societies. Perhaps the first to paint pictures that actually, by reason of their intrinsic merit, raised the Finnish to the general level of European art, was Werner Holmberg, who was born in Helsingfors in 1830. He died in Dusseldorf in 1860, barely thirty years of age.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Obtaining Cross Section of River.

SHIPTON.—M. H. writes: "How can I obtain the cross section of a river when it is not possible to traverse it by a boat?"

In the absence of further particulars as to size of river, &c., we are unable to answer this question, which on the face appears absurd. If "M. H." will send further particulars we shall be happy to help him.

Hip Gutter.

CANTERBURY.—W. W. writes: "I should be glad if you would give a sketch section of a simple and effective form of hip gutter so

HIP GUTTER.

that the slating could be mitred at the hip instead of having a lead or other covering over. In this country this is seldom done, the usual form being lead turned out over the slating with a roll. What is the usual section of this secret kind of gutter, say with a 2in. hip?"

The accompanying sketch shows the method of forming a secret gutter for the hip of a slated roof.

HENRY ADAMS.

New By-Laws.

ELHAM, KENT.—HERBERT writes: "I should be glad to know if a rural district council, which has just sent some building by-laws up for the sanction of the Local Government Board, can compel me to conform with them before they get them returned and the seal affixed?"

No. The by-laws must be under the common seal of the Council (section 182 of the Public Health Act, 1875) and do not take effect unless and until they have been submitted to and confirmed by the Local Government Board (Section 184).

H. P. B.

Safe Load on Cantilever.

BELFAST.—JOIST writes: "What weight will a spruce joist 9in. x 1½in., projecting 2ft., and supported at one end and loaded at the other, carry?"

Breaking weight on a beam supported at both ends and loaded in the middle = $W = \frac{c b d^3}{L}$, where W = breaking weight in cwts.;

c = weight in cwts. required to fracture a bar 1in. square and 1ft. long = 3cwts.; b = breadth in inches; d = depth in inches; L = length in feet. A cantilever of same length and scantling, loaded at the end, is one-fourth as strong; therefore breaking weight on joist 9in. x 1½in., projecting 2ft. = $\frac{c b d^3}{4 L} = \frac{3 \times 1\frac{1}{2} \times 9 \times 9}{4 \times 2} = \frac{729}{16} = 45.5$ cwts. Taking factor of safety at 10, safe load = $\frac{45.5}{10} = 4\frac{1}{2}$ cwts.

HENRY ADAMS.

Projections beyond Building Line.

WALTON-ON-THAMES.—S. A. D. writes: "Smith lays out an estate for building purposes, and on a part of it he builds a house which he sells to Brown. The agreement contains the usual restrictions as to boundaries, sites, values of buildings, &c. Jones also buys two plots and proceeds to erect three shops on them, projecting one side several feet beyond the building line. (1) Is the vendor responsible in any way? (2) Is the act of Jones legal? (3) Is the U.D.C. or their surveyor free from responsibility in the matter?"

We assume that one of the restrictions contained in the agreement was that the purchaser of each lot was not to build beyond the building line. On that assumption the vendor will be responsible if he has by the agreement bound himself to enforce the conditions, but not otherwise. The act of Jones will not be legal, and can be restrained by an injunction at the suit of the vendor or of Brown. The U.D.C. or their surveyor incur no legal responsibility in the matter.

H. P. B.

Elizabethan, Jacobean and Queen Anne Architecture.

GRAVESEND.—VESWOR writes: "I should be glad to have a rather full list of the characteristic features of Elizabethan, Jacobean and Queen Anne architecture. I should also be very pleased to have the title of any book dealing with the above styles very fully."

A most exhaustive account of Elizabethan architecture is to be found in the R.I.B.A. prize essay for this year, which, though not yet published, can be consulted at the R.I.B.A. library. This query could only be properly answered by printing this essay in full, and by adding equally exhaustive treatises on the other two styles mentioned; but probably it will serve "Veswor's" purpose to point out to him that Jacobean work—i.e., the work done under the Stuart monarchs before the time of the great Civil War—was in deterioration of the already debased Elizabethan; while the Queen Anne would include all domestic work subsequent to the Restoration until the middle of the eighteenth century, most of which is solid, brick built, and rectangular, with heavy cornices and good pediments and doorways. The large folio works by Mr. J. A. Gutch and Messrs. Belcher and Macartney should be consulted.

G. A. T. M.

New Streets.

HEXHAM.—W. M. B. writes: "Under what circumstance can a Council legally demand land when building on an admittedly public road that is not of the required width? Is it a question of fact to be decided by different cases? For example, if four houses only were built, would that be different to a row of twenty or thirty buildings? The lane is only 16ft. wide and the Council has regularly kept it in repair, but they wish me to set back half the width of a new street, measuring from the centre of the existing roadway. There is no possibility of anything being built opposite. The lane continues the same width for some distance; could it be made into a new street, or could streets be set off at right angles to it, seeing that the owner of the land has no power to widen it for an entrance to the proposed new street to comply with by-law 8 of the Model Series, which are adopted here. With regard to the decision of Justice Wills on February 23rd, 1893, in the case of *Bromley Local Board v. M. Lloyd* (which, I understand, has been overruled), do you think a by-law providing for an entrance to both ends of the new street, the full width of the street, would be considered good and reasonable?"

We cannot undertake to answer abstract questions such as our correspondent puts. If he will state facts and found a query upon them, we shall endeavour to reply as clearly as possible. The only answer we can give to his first question is that in order to constitute a "new street" there must be a certain degree of continuity in the buildings, if this is the point he wishes to have cleared up. Whether there is, or is not, such continuity is a question

to be decided by the facts of each case. The second question we cannot understand; but see no reason why the lane in question should not be made into a new street. As to the third, we are not aware that the case referred to has been overruled, but must decline to answer a speculative question about a by-law which appears to have no existence.

H. P. B.

Power of Committee to Sanction Building.

PADSTOW, CORNWALL.—INTERESTED writes: "In an urban council district a wooden building has been erected which is to be known as a sailors' rest. When the Council recently held its meeting a member enquired whether the usual notices had been given to the Council, and whether plans had been submitted as required by the by-laws. He was informed that no plans had been submitted, neither had the matter been brought before the Council in any way. The person who put up the building had seen the surveyor and some members of the Building Committee separately, and these gentlemen consented to the shelter being built. By-law 28 says: 'Every person who shall intend to erect any new building shall give a fortnight's notice to the Board of such intention by writing, delivered to the local surveyor or left at his office, and shall at the same time leave or cause to be left at the said office detail plans and sections of every floor of such intended building.' Had the Building Committee any power to give their sanction, not having been called together? Can a member or a minority take any steps to insist on the by-laws being complied with?"

The Building Committee had no power to give their sanction in the way they are described as having done. Even if they had been called together, and had met regularly, they could not have effectually sanctioned the erection of any building in respect of which the provisions of by-law 28 did not comply: *Yabbicorn v. King* (1899, 1 Q. B. 144). A by-law cannot be dispensed with by the public authority which passes it, as the by-law is not made for their benefit but that of the public. The remedy of the minority is by a complaint to the Local Government Board under section 299 of the Public Health Act, 1875: *Passmore v. Oswaldtwistle Urban District Council* (1899, Appeal Cases, 387).

H. P. B.

Chaining on Slope.

BRIGHTON.—W. B. writes: "I should be glad if you would give me a table showing the distance in feet and inches to be added on the ground when chaining on different gradients with a 50ft. chain in order to get a horizontal measurement. What instrument do you consider best to use in order to measure these gradients other than a theodolite? I am in

CHAINING ON SLOPE.

the habit of using an Abney reflecting level for the purposes. Can I do better?"

The amount to add per chain on the ground for any slope can be obtained from the formula $r \sec \theta - r = x$. Using a chain of 50ft., this gives for 2 degrees 0.36 inches.

4	"	1.46	"
6	"	3.30	"
8	"	5.54	"
10	"	9.25	"
12	"	13.40	"
15	"	21.16	"
20	"	38.51	"

Abney's reflecting level is the most convenient instrument for finding slopes in chaining.

HENRY ADAMS.

Correspondence.

Initials L.A.S.M.

To the Editor of THE BUILDERS' JOURNAL.
EDINBURGH.

SIR,—With reference to the reply given on page 77 of your last week's issue with regard to the initials "L.A.S.M.," how would "Land Surveyor and Measurer" do? If this is what they stand for, their use after an architect's name is surely very misleading, as the ignorant would take it for some degree or other.—Yours truly,
J. McA.

Ellipse by Compasses.

To the Editor of THE BUILDERS' JOURNAL.

ASHTON-UNDER-LYNE.

SIR,—In the supplementary article on the above, appearing in your issue for February 28th, Mr. Ramm again asserts that true ellipses may be drawn by compasses and straight edge, and he gives us by way of proof Fig. 15, of which he says: "The curve is drawn by compasses and afterwards tested by finding points in the curve from the foci in the usual way." I, for one, do not admit this as satisfactory proof. In the first place the diagram is too small to prove proper coincidence. Secondly, when the construction used in Fig. 15 is attempted on a large scale, it always fails to bring point C on the minor axis into its proper position. Employing a major axis 3ft. long and a minor axis 2ft. long, point C comes nearly $\frac{1}{2}$ in. short of its proper position, whilst with the same length of axis, and by the methods described for Figs. 3 and 6, page 271 of the issue for December 6th last, other parts of the curve are distorted to nearly the same extent.

I should like to ask Mr. Ramm why eight segments of circles are necessary to complete a true ellipse. If eight, why not six, or even four? The obvious answer is, I think, that the more segments used, the nearer the true curve can be approached, but an infinity of segments cannot theoretically suffice for the reasons given in the previous replies.—Yours truly,
J. A. PERCIVAL.

Valuation of Houses (Repairs and Empties).

To the Editor of THE BUILDERS' JOURNAL.

SIR,—Your correspondent "F. S. I." kindly criticises some points contained in my reply to an enquiry for an example as to the method of valuing house property. I am obliged to "F. S. I." or to any other correspondent who similarly gives attention to these matters from the point of view based upon comparison with his own experience, because it brings into prominence those actual facts which, as "F. S. I." himself hints, are so often hidden by professional men who are less endowed with moral courage than with a desire to effect business to their own immediate pecuniary advantage.

It is as easy though to paint black as to gild; and "F. S. I." whilst drawing a most uncommonly dark picture of the value of house property generally, fails to show why such is estimated at its present value on the market, and is at the same time entirely on the wrong tack in taking the answer I gave as emanating from one whose interest it is to enlarge upon the returns obtainable from investments in house property.

Before entering upon the question of average deductions, I would ask "F. S. I." to consider how it is possible to give figures applicable to the many different classes of this property, to the various localities, and figures equally satisfactory to querists distant hundreds of miles apart perhaps from one's own district—figures which shall represent the so-called fair average. These fair averages are unsatisfactory in that readers are led to apply them to their own particular districts, which may actually need special, and perhaps extraordinary, modifications. I put no faith in averages between figures of so wide range. I would ask any reader to consider the value of an average of figures varying from 2½ to 100 per cent., the range, according to

"F. S. I.," covered by empties and bad debts in actual practice. Would not a so-called average be an exceedingly powerful inducement for a valuer residing either in the exceptionally bad or the very good district to greatly modify his figures? I trust this will suffice to show why, as the facts were with regard to the example I gave, these figures were not put forward as representing in anyway so-called fair averages. The example was for the single purpose of affording an easy illustration of the method of arriving at the nett from the gross value of a house by deducting the specified items, the particular amounts for which might equally have been represented by the letters *x*, *y*, or *z*.

Average figures I must decline to give; but this will not deter me from pointing out to "F. S. I." some little defects in the statements contained in his letter. In the first place, how can we reconcile, with the surprisingly poor returns he puts forward as representative of those from house property, the fact that interests in this class of property are at the present time being so largely entered into simply as speculations?

If the items for each deduction amount to figures such as mentioned in the letter, what equality can the returns be said to bear with the generally accepted percentage expected from house property? Take, for instance, the sum of the several deductions after the averages mentioned by "F. S. I.," and we should have:—

	Per cent. on the rental.
For repairs	25
Empties and bad debts—mean	
of 5 and 12	8½
Rates may be 33 per cent on	
the ratable value which	
equals, deducting ⅓th from	
the gross 33 per cent. on £84	27½

Or a total of 61
without adding anything for reserved or other rent, insurance, &c.

It is very easy to paint the picture black enough, yet house property is paying well and selling well in many districts; and, as showing that the views of "F. S. I." with regard to the matter of repairs do not tally with those of some others, I may quote from that little work on the Rights and Liabilities of Landlords, Tenants, and Lodgers, by De Morgan, in which he roughly estimates "For repairs, insurance, and other expenses (including the periodical expense of external and internal painting about every third and seventh year respectively) to be likely to amount to an annual average sum bearing the proportion of about one-sixth of the amount of the landlord's rent, e.g., a house at a rent of say, £50, may be roughly estimated to have cost at the end of the first seven years of the lease one-sixth of £50 × 7 = £56," this, of course, amounting to 16 per cent., which is to include insurance and other expenses. Mr. Curtis also puts 10 per cent. as the average deduction for house property (see Valuation of Land and Houses, 1899).

I agree with "F. S. I." that it is easy enough to instance particular cases where the repairs have cost nothing for a limited time; but the particular case he cites himself where the repairs for twenty-five years included one item of four times the gross rent and three or four items of half that amount, can only be referred to as very heavy, and showing bad workmanship, or else previous neglect. The large estimates mentioned, moreover, can never be included under the head of ordinary repairs.

With regard to empties and bad debts, as these vary to such an extraordinary extent with regard to the class of tenant and tenement, namely, from 2½ per cent. upwards, as "F. S. I." admits, I fail to see how anyone can venture to estimate a fair average without very precise indications of the value, class, and neighbourhood, etc., and for myself I decline to do so.

Finally, re the deductions for rates and taxes, if "F. S. I." is himself in doubt as to which should or should not be deducted, he will perhaps specify his difficulties more fully in the form of a query. Perhaps, however, having regard to the space which would here be required to enter into the whole question,

"F. S. I." will permit me to refer him to Mr. Curtis's little book on Valuations, and to the authorities and cases cited therein, where he may gather why property tax should not be deducted.

The deduction of £5 for rates and taxes again was merely a hastily assumed figure, not representative of any usual average. The rates to be deducted include:—Poor rate, general district rate, highway rate, school board rate, sewers rate, water rate, and special rates, such as those for lighting in towns, and sea defence near the coast. Taxes also comprise land tax (if unredeemed), Schedule B income tax, house duty, &c.

The local rates again vary to an extraordinary degree, from 2s. 6d. in the £ in some country districts (and half that amount, of course, on land) to three or four times that amount in many towns.

I may quote one example which may perhaps enable "F. S. I." to estimate the approximate average for any similar class of property:—The total rates in the town of Hastings come to about 33 per cent. on the ratable value, i.e., for a house of gross rent, say, £42 and ratable value (deducting one-fifth) = £36, the rating would be £12.

I trust this will suffice to show the folly of setting down any hard and fast rules for the guidance of readers as to the amount of deductions. Such a course would be as misleading to one as helpful to another. I trust also that it will convince "F. S. I." of the fact that the example of mine referred to was not given as one of an arbitrary exactitude in any way, but purely from a desire to furnish the querist with a simple, easily-understood indication of the lines he should follow.—Yours faithfully,
C. BRAND, P.A.S.I.

New Patents.

These patents are open to opposition until April 14th.

1899.—Radiators.—5,107. W. T. SUGG, London, S.W. In order to ensure good circulation, and to allow the parts of the radiator to contract and expand, supplemental tubes are placed inside and concentric with the ordinary pipes, one end being fixed and the other end being free and extending into a chamber at the top or bottom of the ordinary tubes. Expansion steam joints are obviated.

Exterior Lighting.—5,867. H. TALBOT. This invention relates to lanterns having incandescent mantles without chimneys. At the top of the lantern is supported a square enamelled metal plate, having a hole in the centre with a bar across it. It is formed to allow air to pass round its edges, and has an extension or chimney leading to the top of the lantern. By these means gusts of wind are kept out.

Latch Bolts.—6,185. C. R. HECKFORD AND H. BAGNALL; both of Wolverhampton. Instead of having the bolt in one piece, either cast or forged, the back end is made from sheet metal and riveted to the stem. In a modification the stem and back end are both formed of sheet metal. The bolt is claimed to be light and strong, and facilitates fitting.

Hot-Water Boilers.—7,217. B. G. SMITH, Halifax. The boiler consists of a series of large tubes, preferably arranged parallel to each other, with vertical side tubes at right angles. The boiler is covered with a perforated shield to prevent it becoming clogged with dirt and ashes, and screw plugs are provided to allow scale to be removed, which is the essential feature of the invention.

Door Bolts.—8,383. J. BANKS AND J. H. BANKS; both of Willenhall, Staffs. The bolt plate is made from a metal blank which is stamped and pressed out at certain parts to form the staples for the bolt to slide through.

Window Blinds.—13,095. A. W. LOVELAND, Norwich. The blind is made of a single piece of canvas or other fabric, and is creased in accordion fashion. Cords are threaded as in Venetian blinds, and counter-balance weights are provided.

The following specifications were published on Saturday last, and are open to opposition until April 21st. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—3,010, HERBERT and HARMER, lathe chucks. 3,064, HALL, portable theololites, levels, and other surveying instruments. 3,789, HALL, machinery for making slabs with plain or ornamented surfaces of plaster, cement, or composition. 4,057, BROOKES (*Jäger and Seifert*), construction of removable or portable buildings. 5,248, ANDERSON, appliance for recovering the unconsumed fuel from the deposit as it falls from any house fire-grate, effecting a considerable saving of fuel. 5,302, YINGLING, furnace grates. 5,456, JECKEL, method of constructing harbour moles, breakwaters, bridge piers, and other marine constructions, and blocks therefor. 5,526, GOLBY, (*Oertel*) measuring staff, capable of being used as a walking stick. 5,715, CARPENTER and FOWLER, method or apparatus for tunnelling. 5,880, NORTHOVER, bolt for the secure fastening of doors, cupboards and the like. 5,999, KNIGHT, glass-lined artificial stone manholes. 6,413, WEAVER, fastenings for gates, doors, and the like. 6,658 CRANDALL, padlocks. 6,892, ADAM, airing, drying, or seasoning of timber and such like. 6,933, BERGER, acetylene generators. 6,979, TENNANT and STOKES, means for purifying and filtering running water. 7,541, THORNTON, brick presses. 7,561, MORGAN and JEREMIAH, chimney pots. 7,640, GORTON, portable window seats for cleaning, painting, or repairing windows. 7,741, THOMPSON, building brick. 7,815, WILLIS (*Lowery and Billings*), window fasteners. 7,921, CORBETT, couplings for wire ropes. 8,280, OATES, waste-water closets. 8,309, SINGER and MADDOX, process of preparing and putting up colouring matters for use in small quantities. 8,926, STEEL, NUT, and JOSEPH HAMPTON, LIMITED, and HAMPTON, mitre cutting machines. 8,994, OATES, waste-water closets. 10,631, ROBINS, design and construction of wrought-iron and steel pipes. 12,948, LORENZ, stove. 13,626, ROBINSON, apparatus for cutting long shavings into chippings or adzings. 17,876, COOPER, making of moulds for casting metals. 24,148, LUHNE, electric furnaces for making glass and other analogous substances. 24,185, WILLIAMS, water-closet flushing apparatus and the like. 24,651, LAKE (*Woodbury*), flushing apparatus for water-closets and the like. 24,741, EGGEMAN, centrifugal testing machines. 25,027, ALEXANDER, brick-making and pressing machines. 25,195, PHILIPS, wheels or pulleys. 25,196, PHILIPS, wheels or pulleys. 25,361, ISBILLS, curtain fixtures. 25,492, NELSON, HOUGHTON and MILLER, acetylene gas lamp.

1900.—147, TETES and HEANY, electric water filters. 427, BROMHEAD (*Waterman*), process of enamelling. 508, GRAVILL, keyed tile. 819, JONES, roofing and similar tiles. 1,063, PAULS, flushing device for water-closets.

New Building for the Tower Garrison.

—The new building which has been erected for the garrison of the Tower will shortly be ready for occupation. It is five storeys high, fireproof throughout, and comprises a sergeants' mess-room, guard and orderly rooms, and a library and reading room. The building is hemmed in by the "Bloody Tower," the Wakefield Tower, and the White Tower. The style of architecture is Elizabethan and the cost will be over £20,000.

New Covered Market for Hull.—The scheme for providing covered accommodation for those who have stalls in the present open-air market is proceeding satisfactorily. It is proposed to purchase from Messrs. Easton and Sons the property in and behind Trinity House Lane, occupied by Messrs. Shipham and Co., for the purpose of providing further accommodation for the proposed covered market. The property comprises 1,100 sq. yds. and the price asked is £6,650, the vendors paying their own costs and charges in the matter.

Professional Practice.

Hull.—The Hull City Fine Art Gallery will be formally handed over to the Corporation shortly. It forms a sort of top flat to the Museum of the Royal Institution in Albion Street, and it was a condition—rather an awkward one for Mr. Jacobs, the architect—that this upper storey should be placed entirely out of sight, so that it should in no way disfigure the classic façade of one of the few architectural ornaments of the city. This has been admirably done, for the only evidence in the street of the existence of the Gallery is its main entrance, which is placed at the east end of the Royal Institution, and made so much in harmony with that building that it appears to be an extension of the original design. The Gallery is reached by a well-lighted staircase of short easy flights, with spacious mosaic-paved landings. It comprises a principal room, 75ft. by 25ft., and two lesser ones, each 33ft. by 19ft. They are all brilliantly illuminated, and a pleasing feature of the decorated ceilings are the panels supporting the skylights, upon which the city arms are modelled and made the centre of a device. There are, of course, the usual accessories—the secretary's room, the cloak rooms, and the ticket offices—as well as an outside emergency stair and a lift for dealing with heavy pictures.

London.—On Friday last the cheap restaurant in City Road, of the Alexandra Trust (which includes the Princess of Wales and Sir Thomas Lipton) was opened. It has been built from designs by Messrs. Mark King and Co., and its frontage is of Bath stone, with polished red Aberdeen granite. Entering, there is a handsome lobby, with palms, a flooring of mosaic, and the Princess of Wales' cipher and coronet in coloured inlay. In the centre of each hall is the bar and counter, fitted with bright electro-plated service, while pure water drawn from an artesian well 300ft. deep is supplied gratuitously. Three floors are thus similarly fitted, the glazed brick walls, the marble tables, and the mosaic and concrete floors being highly suggestive of cleanliness and sweetness. Women have been particularly well catered for throughout, and in the basement the toilet-rooms provided will be of the utmost convenience to those who come in from the suburbs for their day's work. There is a staff of a hundred waitresses. Each of the three halls can accommodate 500 people, so that 1,500 meals can easily be simultaneously consumed, and 12,000 meals can be provided during the day.

Sheffield.—A new Board school has been built at the top of Daniel Hill from designs by Messrs. Hemsell and Paterson, architects, of Sheffield. The south front faces Daniel Hill Street, from which the site slopes down rapidly, causing the north front to be lofty, and to appear very prominently over the other buildings in the neighbourhood. For this reason, as well as for convenience of plan, this front has been treated architecturally as the principal one. The school has two principal floors, and provides accommodation for 810 children. The ground floor, which is devoted to infants, contains a schoolroom for 120, four classrooms for sixty, and one for fifty, one of the classrooms being fitted up to be used when required for cookery classes for the girls. The upper floor, for boys and girls, contains a schoolroom for 120, three classrooms for sixty, and two for fifty. There are, in addition, three teachers' rooms and the necessary cloakrooms and lavatories. Rock-faced stone from the Bole Hill quarries has been used for the external walls, with Matlock stone dressings, and Westmorland slates for the roofs. The general contractor was Mr. A. Moore, of Sheffield. The heating, which is by hot water on the low-pressure system, has been carried out by Messrs. Wright Bros., of Attercliffe. The site, which is slightly over two acres in extent, cost £2,510, and the building, including fittings and professional charges, cost £9,800. The total cost has been £12,400, or £15 6s. 2d. per child accommodated.

Builders' Notes.

London County Council.—At last week's meeting of the Council the Water Committee recommended: "That, in view of the urgent reasons which exist against further delay in dealing with the question of London water supply, the First Lord of the Treasury be requested to receive a deputation with reference to the London Water (Purchase) Bill and the London Water (Welsh Supply) Bill." This was carried by seventy-two votes to twenty-nine, it being agreed that the words "having regard to the recent report of the Royal Commission" should be added. The Building Act Committee recommended: "That the order of the Council of February 6th, 1900, sanctioning the formation or laying out of two new streets for carriage traffic on the east side of Tottenham Court Road be varied so that the time within which the roadways of the proposed streets to lead out of Tottenham Court Road into Chenies Street and Store Street respectively were required to be clearly defined throughout by posts and rails, or so otherwise as the Council should permit, and thrown open to the public as highways, be extended to three years from the 6th day of February, 1900." This was agreed to.

Workmen's Compensation.—The recent case of *Rixson v. Pritchard and Benwick* was an appeal from an award of the Judge of the County Court of Kent, holden at Dartford. In the High Street at Dartford, next to the Bull Inn, which was a building over 30ft. in height, there stood two buildings less than 30ft. in height, which were formerly shops. The landlord had recently determined to demolish the two low buildings for the purpose of extending the main building of the inn. This work was undertaken by the employers, and the applicant, in the course of his employment, was wheeling some rubbish from the houses which were being demolished when he fell and sustained injuries. The sole question in the case was whether the applicant was employed on, in, or about a building which exceeded 30ft. in height, and was being demolished within the meaning of section 7, sub-section 1, of the Workmen's Compensation Act.—The Court allowed the appeal. Lord Justice A. L. Smith said that the applicant was engaged in pulling down the beerhouse, which was less than 30ft. in height. The only building which was over 30ft. in height was the Bull Inn, and that was not being demolished at all. No part of the building which was being demolished exceeded 30ft. in height. The communication between the beerhouse and the inn did not make the smaller building a part of the larger building.—Lord Justice Collins and Lord Justice Romer concurred. In another recent case, that of *Brady v. Cooper and Crane and Alfred Wright*, the question raised was whether Wright (a tiler and a sub-contractor) was responsible to indemnify the defendants, Messrs. Cooper and Crane, in respect of their liability to compensate the plaintiff, a widow, for the loss of her husband. Lord Justice Smith said the court had decided in the case of *Cass v. Butler* (see page 71 of last week's issue) without doubt that the sub-contractor did not come within the Act, because he could not be said to be the "undertaker," although the employer of the injured man. The only person who could be held liable was the "undertaker" who constructed, repaired, or demolished a building. That being so, Messrs. Cooper and Crane were undoubtedly "undertakers." Wright was simply a sub-contractor employed by them to tile the building which they had undertaken to construct, and, therefore, it was impossible, in his opinion, to hold that Wright was the "undertaker" within the meaning of the Act. This appeal must be allowed with costs. Lord Justices Collins and Romer concurred.

Electric Launches on the Venice Canals are being tried. They will be much more suitable than the old smoke-producing steamboats plying up and down the Grand Canal.

Surveying and Sanitary Notes.

Extensive Street Improvement Scheme at Paisley.—The Paisley Police Commissioners have decided to widen Causeyside, which leads from the cross to the south end of the town, to 80ft. The scheme will cost £82,300, including an improved gradient.

Development Scheme at Felixstowe.—The Coast Development Company are about to open up a large area of land at Felixstowe which has been purchased from Captain Pretymann, M.P. Plans have been prepared and the first portion of the land acquired will be offered for sale next Easter.

Leeds City Square Statues.—It is not probable that the statues for Leeds City Square will be unveiled this year, owing to the prolonged illness of the sculptor who has been given the commission—Mr. Brock. He has now, however, so far recovered as to be able to continue what he has determined shall be the greatest work of his life.

Inspectors of Nuisances.—The following resolutions were passed at a meeting of the Executive Council of the County Councils Association: "That it be represented to the Local Government Board that all inspectors of nuisances should hold certificates of efficiency before the approval by the Board of their appointment." "That it be represented to the Local Government Board that it is desirable that County Councils should have an opportunity of objecting to the approval by the Board, at his first appointment, of any sanitary officer to whose salary the Board contributes."

Holborn to the Strand Thoroughfare.—At a dinner held last week by the members of the Improvements and Finance Committee of the London Corporation, Mr. John Piggott pointed out that after all, in point of area, the city was only the size of a small farm, namely, some 700 acres. The chairman (Sir Robert H. Rogers) said that the County Council would acquire for the new street from Holborn to the Strand property of the value of £4,700,000, and expected to recoup themselves to the extent of £4,000,000. The ground rent of the surplus land would be £117,000, while the interest on the outlay would be only £132,000, and consequently there would be a difference to the credit of the improvement of between £12,000 and £14,000 per annum. It was estimated further that at the end of eighty years the Council would be in possession of eight millions through this improvement alone.

Trade and Craft.

Silicate Cotton.

The uses of silicate cotton are many and various, but for the architect it has special interest as a material for fire-, sound-, or heat-proofing floors, walls, partitions, &c., for lining roofs and for insulation purposes in cold stores. In matters of insulation it is as true as is everything else, that good quality is good economy, for if the insulating material is imperfect there will be a constant loss of power which might have been saved had there been a little less parsimony in first cost. British-made silicate cotton was patented and introduced by Messrs. Frederick Jones and Co., of Perren Street, Kentish Town, N.W., about twenty years ago, and it is made by converting blast furnace slag, whilst in a molten state, into fibres. By this process its bulk is increased twelve-fold, and it is directly, because the air it contains is "still," that it is such an excellent insulating material, as the larger the space the more the air moves—resulting in poor insulation. The other qualities of silicate cotton may be summed up thus:—It is fireproof, imperishable, vermin-proof, will not become musty, does not absorb moisture, does not (on account of its fibres) fall through the matchboarding and injure the refrigerated goods, does not "silt," and is reasonable in price. Its average density is about 12 per cent. less than flake charcoal. Out of a long list of cold-air stores where silicate cotton has been used, the following may be mentioned:—Edinburgh Ice Co., Edinburgh; Hagerup, Doughty and Co., Great Grimsby; Hastings Ice Co., Hastings; Venner and Sons, Southampton; North-Eastern Railway Co., Hull; Malvern Ice Co., Malvern Links; Worcester Pure Ice Co., Worcester; Exeter Ice Co., Exeter; Croydon Pure Ice Co., Croydon; and Sawers, Ltd., Glasgow. The firm has branches at Glasgow, Leeds, Liverpool, Newcastle-on-Tyne, Swansea, Middlesbrough and elsewhere.

William Black Memorial.—The plans are now out for the erection of the William Black Memorial Tower at Duart Point, on the Island of Mull, west coast of Scotland. The tower is intended to serve as a beacon for the guidance of mariners.

New Exeter Hotel.—The new Franklin Temperance Hotel, in Fore Street, Exeter, was opened last week. Mr. Harbottle Reed, of Exeter, was the architect for the alterations, and Messrs. Westcott, Austin and White were the contractors.

Keystones.

Almington Hall, a fine old mansion two miles from Market Drayton, Shropshire, was totally destroyed by fire on March 7th.

The Royal Birmingham Society of Artists has re-elected Sir W. B. Richmond, R.A., as president for the ensuing year.

New Sanatorium for Consumptives.—On Thursday last a sanatorium for consumptives, the first of a public character in the kingdom, was opened at Meathrop, Westmoreland.

Archæological Discovery in Whitehall.—In the course of the excavations on the site of Carrington House, in Whitehall, for the new War Office buildings, the remains of several well-defined roads have been laid bare.

New Technical School for Burnley.—The Burnley Town Council has decided to proceed with the erection of a new higher grade and technical school, and to invite competitive plans. The total number of students to be accommodated in the new institution is 1,208, and the estimated cost is £40,000.

Architectural Museum, Westminster.—We note in the "Times" that Mr. Maurice B. Adams, F.R.I.B.A., honorary secretary of this museum, says in his reply to the statements of Mr. Max Judge (see page 75 of last week's issue): "If we kept the museum open without having the school of art in connection with it the annual deficit could not be less than £300. It is utterly untrue that the institution has fallen into decay . . . before we can overhaul or revise the collection we shall have to expend a considerable sum in repairing the roof, and subscriptions will be most welcome for that purpose. A little help is worth a lot of fault-finding."

Workmen's Compensation.—The case of *Fenn v. Miller* was heard in the Court of Appeal on Saturday. Mr. Miller was building some houses at Chingford, and Fenn was a workman, whose duty it was to assist in making the mortar. There was a steam engine in a shed for this purpose. Fenn went with a horse and cart to a brook to get some water, and, when returning, the horse took fright and Fenn was knocked down and injured—being then 487 yards from the nearest building in course of erection, and about 200 yards from the engine shed. The County Court judge found that the shed (owing to the engine) was a "factory," and that the accident happened "about" the "factory." The Court, however, did not agree with this, and allowed the master's appeal.

Chichester Cathedral.—It is stated that a sum of £9,000 is still required to complete the rebuilding of the north-west tower.

The Royal Hibernian Academy opened its seventy-first annual exhibition of paintings on March 5th. There are 349 exhibits.

The death is announced of Chancellor Ferguson, of Carlisle. He was a zealous antiquarian, and took a great part in the excavations at Furness Abbey.

An Arts and Crafts Exhibition at Warrington has been opened in the Parr Hall, and will remain open during the greater portion of this month.

Improvements at Bournemouth.—The Bournemouth Town Council has appointed a committee to prepare schemes for the erection of a summer and winter pavilion at the shore end of the pier. The estimated cost is about £25,000.

Yost Typewriters.—A record shipment of nearly 120 Yost typewriters was effected a week or so ago to the order of H.M. Government. This breaks all previous records, and evidences the growing popularity of the typewriter in Government offices.

New Window at St. Paul's.—The window now in progress of erection in the north end transept of St. Paul's Cathedral is the gift of the late Duke of Westminster. Sir W. B. Richmond, R.A., K.C.B., has executed the design.

A new Presbyterian Church at Blackburn is being built at a cost of £5,000. The site is at the junction of Bangor and Troy streets. The nave of the church will be 64ft. long and 48ft. wide. The seating accommodation will be for 580 persons on the ground floor and 80 in an end gallery. The church will have an open timbered roof, and is in the Perpendicular Gothic style. Mr. Dixon is the architect.

British Association President.—The Council of the British Association has nominated Professor A. W. Rucker as president of the Glasgow meeting in 1901.

Bath's New Art Gallery.—The municipal institutions of Bath have been enriched by the taking over by the City Council of the art gallery, which is to serve as the city's permanent memorial of the Queen's Diamond Jubilee.

A new Parish Church at Glasgow has been built at the corner of Rutherglen Road and Rose Street at a cost of £7,000. Accommodation is provided in the church proper for 950 persons, and there is an adjoining hall with a seating capacity of 600.

Alexandra Palace.—The Wood Green District Council has decided to contribute £25,000 towards the Alexandra Palace and Park Purchase Fund. Hornsey and Wood Green have between them given £55,000 towards the £120,000 required for the purchase.

Homes for Convalescent Children.—At last Saturday's meeting of the Metropolitan Asylums Board plans were adopted for the Millfield Homes for 100 convalescent children, proposed to be erected at Rustington, near Littlehampton, at a cost of £17,975. The plans will be sent to the Local Government Board for approval.

Further Discoveries at Furness Abbey.—Further excavations at Furness Abbey, undertaken under the auspices of the Cumberland and Westmorland Antiquarian and Archaeological Association, have resulted in the discovery of three distinct floors in the chancel—first the early Norman, then a second 18in. higher, with a beautiful tiled floor, and a third floor, 3ft. higher up. The excavations prove how sound and perfect the red sandstone foundations of the building are.

Proposed New Lock at Grimsby.—A scheme is on foot for forming a deep-water lock at Grimsby at a cost of between four and five millions sterling.

Lincolnshire County Asylum.—At a special meeting of the Visiting Committee of the Lindsey, Lincoln, Grimsby, and Holland Asylum, held last week at the Asylum on Bracebridge Heath, it was reported that the existing accommodation was not available for more than 680 patients and attendants, and Mr. A. E. Gough, architect, had prepared two alternative sets of plans, each providing accommodation for a total of 1,000 in an extensive block of administrative buildings on the northern side of the existing buildings. The plant marked A, and roughly estimated to cost £55,000 or £60,000, was adopted.

Basement and Similar Lighting.—The legal battles fought over the question of ancient lights must surely be legion, but the attempt to produce more light is not so frequently heard of. A considerable success has, however, been achieved in this direction by the Union Plate Glass Co., Ltd., of St. Helens, whose advertisement in the current issue shows the change made in the appearance of a room when their "Refrax" glass is used in the windows. We have recently seen this glass in an experimental room, and can testify to the difference made when a window of "Refrax" is inserted in the frame in place of one of ordinary glass. The glass is already largely used for lighting basements, underground schools, &c., and its success is amply proved by the altered conditions under which work is carried on. In many places daylight now takes the place of the continual gas flare, solely owing to the use of this new glass. The effect it produces requires to be really seen, for, apart from actual demonstration, few would believe it possible to effect such an improvement in so apparently simple a matter as the lighting of a room.

The Comédie Francaise in Paris was destroyed by fire on Thursday last, and the loss in archives, valuable pictures, busts of famous dramatists and players, is considerable. The cause of the fire was the defective condition of the heating apparatus, the pipes being choked with soot.

Turner's Picture, "The Grand Canal of Venice," which was bequeathed to the Metropolitan Museum of Art in New York by the late Mr. Cornelius Vanderbilt, has been placed on exhibition. The sum of £20,000 is said to have been paid for it by Mr. Vanderbilt.

Westminster Abbey Crumbling Away.—In a lecture delivered on Thursday at the Chapter House, St. Paul's, Mr. J. T. Micklethwaite, the new surveyor of Westminster Abbey, stated that the old stonework of the Abbey was fast crumbling to pieces, owing to the fumes of the works on the other side of the river.

Drawings of the Recent Excavations of Pompeii.—The authorities of the Victoria and Albert Museum have specially lent to the Birmingham Museum and Art Gallery a collection of water-colour drawings by the well-known Roman artist, Luigi Bazzani, of the latest excavations at Pompeii, including the magnificent house of Vettius, and the very beautiful mansion known as the Nozze d'Argento.

COMING EVENTS.

Wednesday, March 14.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Professor Henry Robinson, M.I.C.E., on "Sewerage and Sewage Disposal," 8 p.m. Inspection and demonstration in the parish of St. George's, Hanover Square, at 2 p.m., conducted by Mr. Albert Taylor.

RUSKIN SOCIETY OF BIRMINGHAM.—The Rev. Canon H. Scott Holland, M.A., on "Oxford in the Forties and in the Nineties," 8 p.m.

EDINBURGH ARCHITECTURAL SOCIETY.—Professor G. Baldwin Brown, M.A., on "The Sculpture of the French Gothic Cathedrals," 8 p.m.

BIRMINGHAM AND DISTRICT CLERK OF WORKS AND BUILDERS' FOREMAN'S ASSOCIATION.—Mr. T. G. Price, A.R.I.B.A., on "Rome," 8 p.m.

NORTHERN ARCHITECTURAL ASSOCIATION.—Annual meeting at 7.30 p.m., to view Students' Drawings, to receive Annual Reports, and to elect Auditors. Sir Benjamin Chapman Brown, D.C.L., will present the prizes to the successful Students.

INSTITUTE OF SANITARY ENGINEERS.—Meeting of Examination and Literary Committee at 2.30 p.m., of General Purposes and Finance Committee at 3.30 p.m., and of Election Committee at 5 p.m. Mr. Wm. Strachan on "The Construction of Water-tight Sewers and House Drains in Water-logged Ground" at 7 p.m.

Thursday, March 15.

SOCIETY OF ANTIQUARIES OF LONDON.—Meeting at 8.30 p.m.

ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Arthur Thomson, M.A., M.B., on "The Anatomy of the Human Form: The Connection of the Head with the Trunk; the Structures which Determine the Form of the Neck," 6.15 p.m.

ROYAL INSTITUTION.—Mr. Charles Waldstein, Litt.D., Ph.D. L.H.D. on "Recent Excavations at the Argive Heraeum (in Greece),"—III. 8 p.m.

Friday, March 16.

ARCHITECTURAL ASSOCIATION.—(Discussion Section.)—Mr. W. E. Dobson on "The Church of San Francesco, Assisi: a Study in Colour Decoration," 7 p.m.

ROYAL INSTITUTION.—Sir Benjamin Stone, M.P., on "Pictorial Historical Records," 9 p.m.

ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Lewis F. Day on "Ornamental Design,"—XI. 11.30 a.m.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Mr. Charles Jones, M.I.C.E., on "Scavenging and Disposal of House Refuse," 8 p.m.

INSTITUTION OF CIVIL ENGINEERS.—Students' Visit to the Cathedral Works in progress at Ashley Place, Westminster, at 2.30 p.m.

Saturday, March 17.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Inspection and Demonstration at the Sewage and Destructor Works, Ealing, at 2.15 p.m., conducted by Mr. Charles Jones, M.I.C.E.

PEOPLE'S PALACE ARCHITECTURAL SOCIETY.—Mr. Tanner on "History of House Drainage," 7.30 p.m.

BRITISH INSTITUTE OF CERTIFIED CARPENTERS.—Visit to the new Cathedral, Westminster, at 3.30 p.m.

Monday, March 19.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—Mr. J. Fletcher Moulton, Q.C., M.P., F.R.S., Mr. J. Douglas Mathews, and Mr. Beresford Pite on "Ancient Rights," 8 p.m.

MORRISON & INGRAM'S SANITARY APPLIANCES.

The "Densitas" Closet Suite

Comprises an excellent wash-down, deep-seal Closet, made in Midway Caneware, double thickness, buff out, white glazed inside, deal seat, 2½ gallons, strong Caneware Cistern, with cast-iron cover and brackets, also wrought-iron flushing pipe, 2ft. long.

Price of Suite Complete, **48s. 7d.**

CARRIAGE PAID.

These closets are expressly designed to save cost in fixing, and are suitable for Workmen's Dwellings, Schools, Warehouses, and the like. They are confidently recommended; also made in finest Porcelain-ware—white, printed, or decorated—for cottage and villa use.

* Revised tender of £730 accepted.

COMPETITION.

ADMINISTRATIVE COUNTY of the ISLE OF WIGHT, TO ARCHITECTS.

The Technical Education Committee of the County Council of the Administrative County of the Isle of Wight invite DESIGNS for a BLOCK of BUILDINGS, comprising a Public Library and Reading Room, Technical Institute Offices, Caretaker's Residence, &c. A lithograph plan of the site, with sketch showing approximately the accommodation required, and instructions to competitors, will be forwarded on application to the undersigned.

THE IDEAL FITTER.

An illustrated Catalogue,
Price List and Reference Book
for Heating Engineers.

JUST ISSUED.

SEND FOR COPY.

The cost of the buildings is limited to about £6,000. Premiums of Fifty Pounds each will be given to the authors of the two Designs considered by the Committee as the first and second in merit, which designs will become the property of the Council. The author of the Design considered the best shall, if required by the Technical Education Committee of the County Council, furnish the necessary contract drawings, with details, and specification, for the purpose of obtaining Tenders to execute the work, for which, if so required as aforesaid, he will be paid 2½ per cent. on the estimated cost. If employed to superintend the works such 2½ per cent. and the premium of Fifty Pounds to merge in the usual

architect's commission of 5 per cent. on the cost, which shall include the necessary detail drawings, copies for contractor and clerk of the works, superintendence, and all expenses.

All designs to be sent, in accordance with the instructions, to the undersigned on or before APRIL 30th, 1900.

WILLIAM H. WOOLDRIDGE,
Clerk to the County Council.
County Council Offices,
Newport,
Isle of Wight,
February, 1900.

EFFINGHAM HOUSE,
ARUNDEL STREET,
STRAND, W.C.

An Architectural Causerie.

The Gothic House. IN the days when Gothic revivalists were full of hope and enthusiasm, there was one aspiration shared by all of them alike which none could claim to have realised; all believed that the modern Gothic house was possible, and several tried to build one; but they never came within measurable distance of success. Nobody is likely to make such an attempt to-day; and, if anyone should, it is not likely that he would be satisfied with the result. With churches it is very different; they may be cold, uninteresting and formal, but the application to them of Gothic forms does not seem anything unreasonable. It may be of some interest then to enquire whether there is any substantial reason why Gothic work seems suitable in a church and unsuitable in a house; for, seeing that people in the Middle Ages had houses as admirable in one way as their churches were in another, it seems at first glance remarkable that we should not be able to imitate both equally well.

From one point of view the period which elapsed between the supersession of Gothic architecture in the sixteenth century and its revival in our own shows a gradual assimilation of modern building to ancient forms. Certainly Chambers' work is more Roman than that of Elizabeth's time; and as the years have removed us further and further from the period when Gothic architecture was living, and archæological research improved our knowledge of ancient building, our work being inspired rather by ancient precedent than present need has perhaps become less straightforward and less sensible. No doubt there is much that is true in this view, but the progress of formalism did not altogether preclude a substantial advance in the arts of designing and building. Indeed, there are many ways in which the Classical style introduced from Italy rather furthered than otherwise the development of a system of planning and construction which should be suitable to our altered requirements.

So the modern designer inherits a number of expedients whose aid he will not willingly forego, but, seeing that these expedients have been introduced under the patronage of Classical art, they will be likely to clash with Gothic forms, and this is, in fact, what generally happens; designers attempt to combine the advantages of a Classic building with the forms of Gothic work, and the birth, as might be expected, is usually monstrous.

The enthusiastic Goth, perhaps, will hardly allow that Classic architecture introduced any

features of substantial utility, nor, indeed, would that incorrigible theorist Fergusson. They regard Classic art as a system of designing envelopes into which rooms and staircases have somehow or another to be squeezed. But may it not be the case after all that the arrangements which suit the classic envelope are in many ways an improvement on those of the middle ages? Take, for instance, the low-pitched slated roof to which the Gothicists object so strongly. It has the undeniable advantages of lightness and cheapness; yet in all probability it would not have been used so commonly in this country but for the Classic style to which a low-pitched roof is proper. Again, everyone will admit that the flat plaster ceiling is the best thing for an ordinary living-room with another storey above it, and though I am not aware that the Romans used such things, the builders of the seventeenth and eighteenth centuries treated

which shall be definitely Gothic; to give up sash windows, plaster cornices and ceilings, architraves and door-linings; then we may get such a house as might really have been built in the Middle Ages, dry and archæological, perhaps, but at least having the merit of consistency.

The other course, and the one generally taken, is to preserve the useful features which Classic architecture has given us and try to make them look Gothic; sash frames are hidden behind stone mullions; flat plaster ceilings with cornices are used, but the cornices given a quasi-Gothic section; all that is altered, is, in fact, the merely ornamental part of the building, so that the house is Gothic only skin-deep; the main lines of its construction are Classic. The inevitable result of these conditions is an incongruity which debases the Gothic style itself; so that it is now fallen into such disrepute that good house architects avoid it like the plague. Yet I cannot doubt that if anyone should have the courage to build a house that was Gothic in its principles as

HIGH STREET, CHIPPING CAMPDEN. FROM A PENCIL DRAWING BY ARTHUR J. GASKIN, STUDENT OF THE BIRMINGHAM MUNICIPAL SCHOOL OF ART.

them so well that they became an integral part of the style. Sash windows, too—who would be without them; and there is no doubt that the square-headed Roman openings take them far better than the arched Gothic ones. But to multiply examples is tedious; after all, it is not unnatural that improvements in building should have accompanied a constant rise in the standard of comfort, and, if the Classic style had been incompatible with these improvements, surely it would not have endured so long.

The Classic builders, then (working, of course, on materials supplied them from the Middle Ages), have equipped us with an excellent method for dealing with most of the features of a house. Hence, if we wish to design a Gothic house, we must take one of two courses; we may reject these methods and use no feature not known in the Middle Ages. This, surely, is the true way of designing if we set out to build something

well as in its trimmings, that feeling would be altered; perhaps we might return to the idea of basing our work on Gothic rather than on Classic; for base it on something we assuredly do and shall.

E. B. S. S.

Four Doomed Theatres.

WITH the beginning of the County Council's Holborn to Strand improvement will come the end of four London theatres—the Opera Comique, Globe, Olympic, and the Gaiety. That these will all be replaced we do not know, but that the Gaiety will rise again is certain, because the Council has agreed to provide a new site for the reincarnated house presently to be demolished. It is not too much to say that London will gain by the sweeping away of these four

houses of entertainment. They—even the best of them, the Gaiety—have outlived their time, and are alike inconvenient for the audiences they are supposed to accommodate, and dangerous for all who frequent them, by reason of being hemmed in by property liable at any time to become the scene of a great conflagration. The Opera Comique and the Globe both date from 1868, and are remarkable for being, alone among London theatres, built back to back, a party-wall only serving to separate their stages. Like their near neighbour, the Olympic, they are certainly not acquisitions to London street architecture, and no one need deplore their coming destruction. It is perhaps little known that the frontage of the Opera Comique to the Strand is, in point of fact, a false one, and that it is only the opening of a long passage which dips down under Holywell Street and conducts to the theatre, itself situated in the block of houses between Holywell and Wych Streets. The sum of £40,000 has been awarded by the arbitrators from the Council to the freeholders, who claimed £60,000. What would they have claimed had these things come to pass in the days of the little theatre's prosperity, from 1877 to 1882, when the early operas of the Gilbert and Sullivan series were drawing the town and bringing crowded houses? When the Savoy was opened, towards the autumn of 1882, the Opera Comique fell on less prosperous and more chequered days. The Globe has been more successful. Built in the vast pit dug for the foundations of a projected (and eventually unsuccessful) scheme for a gigantic Strand hotel, it did not, it will thus be seen, start with the best kind of omen. Fronting on to Newcastle Street, its first tier of boxes is underground, just below the level of the pavement. Despite the many tinkering and re-decorations it has undergone, the interior of the Globe is barn-like and draughty.

The Olympic is the second theatre on that site. The first was built at the beginning of the century on the ground just previously occupied by the old mansion of Craven House, and was curious as having been largely constructed from the timbers of a captured French battleship, the *Ville de Paris*, in which William the Fourth had learnt seamanship in his youth, as a midshipman. That house was built by Philip Astley, of Astley's theatre, as the "Olympic Palace." Perhaps it was because the public did not understand the allusion to the classic Olympian games that this half theatre—half circus—failed to pay. Some years later, it was taken by Elliston, and in the thirties and the forties became the scene of the many triumphs of Madame Vestris. Burnt down, it was speedily re-opened, but lost its favour, and has had but short and fitful gleams of prosperity since then. There is an air of sordid wickedness about the exterior of the Olympic and the neighbouring purlieus of Wych Street, Newcastle Street, and Drury Lane, which leads the Londoner to rejoice that the end of the district is at hand.

Of the Gaiety, which was reconstructed out of the old Strand Music Hall so far back as 1868 by the late Mr. J. S. Phipps, there is little to be said, save that it does not, at this time of day, come up to the requirements of the public. It is one of Phipps' earliest and least successful designs. He had an extraordinarily successful career as an architect of theatres, London and provincial, and practically held the monopoly of this exceedingly specialist work; but although there are some not unpleasant works of his, there are none of them quite in accord with modern ideas, save perhaps his last—Her Majesty's, in the Haymarket. The new street, with the new theatres that will doubtless be built, should serve to give the younger men their chance.

C. G. H.

On Reflection.

The Abuse of Street Facades.

IT is sad to look at the majority of modern street frontages. To any one possessing an artistic perception they are a mass of incongruity and discord. Putting aside the question of architectural design, what need is there to destroy a possible charm or accentuate a very probable eyesore by covering the front of our street buildings with huge and hideous letters? These are the days of gigantic monopolies, and the spirit has infected commercialism and business to such a degree that nothing that is less than a colossus in some way or other can expect to attract attention; and the idea is thus prevalent that unless a shopman covers the front of his premises with letters several feet long he will be lost in the crowd and will lose custom. But things have come to this climax, that as everyone's name is set forth in these large letters a newcomer who would make himself prominent must have his name in letters larger than any around him. A competition in big letters ensues, and see the result! Take a walk down the Strand, for instance (and this is by no means an exceptional example), and you will find it hard to discover a house that is not marred by this miserable lettering fever; and, to make things worse, the letters not only extend along the top of the great sheet of plate glass that forms the base front of the building, but are distributed wholesale over the entire façade. If you want a glaring example of this modern bad taste, compare an engraving of Ludgate Hill from the Circus a hundred years ago with the Ludgate Hill of to-day, and you will see that the former had a rest and harmony of its own, while the latter is chiefly composed of an ugly railway bridge and signals and a range of great letters. There is only one consolation; that is, these letters serve in many cases to cover over the bad architecture. But there is only little comfort in this, and it will be a happy day when small shop titles take the place of those which we now see on every hand.

Reflection in Art.

A MAN'S work without reflection is an empty thing, a hollow ball, a shell without its kernel; so that the presence of the reflective spirit is essential in all that can claim to be of real value. There are, however, limitations to reflection, stages at which it should cease, and it is with these points of arrest in art reflection that it is now the object to deal. Reflection ought always to follow knowledge if it is to end in good results, for, if a man keep thinking in ignorance of that which he would abandon with greater knowledge, his time is indeed ill-appropriated. Shakespeare gives a good example of the evil effects of over-reflection in the much-debated character of Hamlet, who, it will be remembered, keeps putting off the act of vengeance which he clearly recognises to be his duty by morbidly thinking of this and that when he ought, following his convictions, to have been acting. Artists (using the word in its wide meaning), being of a temperament which tends to make them men of thought rather than men of action, require to exercise a special surveillance in order that they may not fall into this mistake. Napoleon's was a good test

in many ways when he demanded first of every man "what he had done." It is to be regretted that the number of the "might be's" is so large, for we all know of persons who either from too much or too little reflection slide down with the human tide either as brilliant bubbles on the surface or heavy logs below. How many are the architects who are for ever planning some glorious structure of which never a stone is laid; while, all the time, the accomplishment of a humbler idea is within their reach. It is, of course, quite possible that this want of action may be due to weakness in character, but even amongst strong men the same characteristic is seen, and it is then generally the result of over-reflection. The true ideal of all, especially artists, architects and craftsmen, should be one of fact, not a flimsy, misty creation with no bottom on the earth. Of what use is the poet whose fancies, however delightful or elevating they may be, lead him to keep the pen away from the paper when it ought to be working there? And an architect of a similar type, the man who dreams away a practice, is he not much at fault? Yet it is the men of this type who never cease to sneer at his more matter-of-fact brethren who are doing something. Of course, the other extreme, that taken by those men of action whose work is unimaginative, tasteless, and lacking in reflection, is equally (if not more) deplorable. But there is a happy medium which the really great must always reach, where the fact and the fancy are mingled in well-judged proportions, and neither is allowed to drag the other into a region of poetical unreality or "earthy" commonness.

Small Gardens.

WHILE architects of note have devoted much time to the designing of gardens for their mansions and palaces, the humbler architect does not apply the same spirit to the smaller buildings erected under his supervision, and it thus happens that we rarely see a small house with a tastefully laid-out garden. This is to be regretted, for the minor practitioner has here a chance of effecting a most appreciable and pleasing change. It is a common plan when, for instance, an estate is being laid out, to divide up the land into rectangular plots, put up a house at one end of each, and leave the rest to Time and a piece-work gardener, and many a house is in this way robbed of a charm which it might possess were its surroundings more in keeping with itself. The argument against this practice is that laying-out the gardens of small houses costs money, and the property cannot stand the expense; but the extra cost would be little in excess of that now incurred, the improvement being effected simply by a judicious and artistic arrangement of the paths, beds, and shrubs, together with such woodwork as might be required to shut off certain parts of the gardens. Again, it is a common thing now to see a row of houses each with a small front garden that is quite too small to be effective. In these cases it would be more satisfactory if all the divisions between these tiny gardens were removed and a long patch of green set out along the whole front of the row, with paths leading to every door. This has been done in many cases, and with good results—through the foresight of the architect; and it would be well if back gardens received the same care, and so became a great deal more artistic than they generally are at present. It is certainly a mistake to think that because they are small they are not deserving of special attention.

DESIGN FOR PANEL. BY GERTRUDE M. BRADLEY.

BIRMINGHAM MUNICIPAL SCHOOL OF ART.

By E. PRESTON HYTCH.

(Concluded from page 85, No. CCLXVI.)

IT is an important circumstance that many of the teachers at the Birmingham Municipal School of Art are directly connected with local industries. At the present time eight of the teachers of the branch schools are engaged in the metal trades, five are architects, two lithographers, three stained-glass workers, two book illustrators, and one is a wood-worker. The headmaster, Mr. Edward R. Taylor, acts as referee for the teaching of drawing in the two high schools and the seven grammar schools of the King Edward's Foundation; and every year examines in drawing all the pupils of those schools. Most of the art teachers in those schools have been trained in the Birmingham School of Art.

At the Central School, morning, afternoon, and evening classes are held, on five days a week, for forty weeks in the year; there is also a class on Saturday afternoons, mainly intended for such students as wish to work in colours, and as could not otherwise receive instruction by daylight. The curriculum includes all branches of drawing, shading, painting, design, and modelling; geometry, perspective, and sciography; architecture and building construction. In addition to these subjects, qualified students are enabled to carry out their own designs, and to receive the necessary technical instruction in the following processes: Repoussé and kindred subjects, e.g., niello, chasing, etching and engraving on metal, damascening, filigree, and metal casting; enamelling: cloisonné, champlevé and Limoges; wood and stone carving, drawing for book illustration, wood engraving, embroidery and other needlework, terra-cotta, silver casting, die-sinking, encaustic painting, leather-work, the making of decorative cartoons, and working in fresco, gesso, tempera, oils, sgraffito, lithography, &c. Craftsmen, designers, architects, and others thus have the opportunity, not only of studying design, but of actual practice in executing their designs in the respective materials. Apart from the ordinary class meetings, thirty lectures on different branches of art are every week given in the Central School.

As to the class of students in attendance, all the students of the branch schools are artisans; and the great majority of them

directly apply to their trades the knowledge which they acquire in the classes. Most of the students of the Central School also are artisans. The students there include architects, builders, designers for all local manufactures, artists in stained glass, brass-workers, iron-workers, die-sinkers, modellers, lithographers, draughtsmen, house-painters and decorators, persons in training to become art teachers, &c.

The total number of individual students under instruction during the autumn term, 1884, was 846; in the autumn term, 1885, on the transfer to the Corporation, it was 1,439; and this number has gradually increased until during the session 1899-1900 it has reached 4,100.

Much help is given to deserving students by the schemes of free admissions and scholarships; and it is possible for a pupil not only to be taught drawing and kindred subjects without the least conflict of method, from the most elementary to the most advanced stage, but to receive that instruction practically without cost to himself. At the present time there are more than 600 free admissioners to the branch schools under the scheme for the award of free admissions to the older pupils and to the ex-pupils of all public elementary schools within the city; twelve free admissioners, under the "William Middlemore" bequest, to the evening classes at the Central School; the following free admissioners and scholars under the scheme provided by the late Miss Ryland, namely: forty free admissioners to the branch schools, fifty free admissioners to the evening classes at the Central School, twenty free admissioners to all the classes at the Central School, and fourteen scholarships, with free admission to all the classes at the Central School, of a total annual value of £170; and one scholarship, with free admission to the Central School for three years, given by Sir Richard and Mr. George Tangye, in memory of the late John Skirrow Wright, and of the total monetary value of £180. A "J. S. Wright" scholar has recently studied for one year in Paris, agreeably to the conditions of that scholarship. In addition, the Committee have adopted a scheme under which they award, in each year, twenty-five free admissions, tenable for two years, to all the classes at the Central School; the competition is limited to such pupils or ex-pupils of the public elementary schools within the city as are under sixteen years of age, and as are exempt from attendance at day schools.

The finished studies executed in the schools are annually forwarded to the Government Department of Science and Art, South Kensington. In the national competition of all the

schools of art in the United Kingdom, 1899, the Birmingham School obtained, for the ninth successive year, a larger number of awards than any other provincial school. Each of the advanced departments in the school is usually represented in the list of national awards. To take a typical year: in 1896, Messrs. H. H. Armistead, R.A., T. Brock, R.A., G. J. Frampton, A.R.A., W. Goscombe John and Hamo Thorneycroft, R.A., the examiners in modelling and modelled design, gave twenty awards in these subjects to students of the Birmingham School. Twenty awards were gained for design, drawn or painted. The Hon. John Collier and Messrs. E. Crofts, A.R.A., A. Hacker, A.R.A., Seymour Lucas, A.R.A., and W. F. Yeames, R.A., awarded fifteen medals and prizes for drawing and painting from the life and antique; Professor G. Aitchison, A.R.A., and Mr. T. G. Jackson, R.A., no less than seven silver and two bronze medals and three national book prizes for architectural drawing and design. For painting from still life and for interiors, Messrs. E. F. Brewtnall, R.W.S., G. D. Leslie, R.A., and W. F. Yeames, R.A., gave four awards; whilst three were obtained for pen and ink sketches, and two for studies of historic ornament. Further, in the personal (or time) examinations in art 3,230 successes were obtained in 1899, against 2,429 in 1896.

It will be seen from the above-mentioned facts that the work of the school, affecting all classes of the community, has not only a great educational influence on the city, but has a direct bearing upon the value and prosperity of the manufactures of the district. Indeed, the scope of the work done gives to the school a position absolutely unique in Great Britain. The gross annual expenditure on the central and branch schools is £15,211; the annual income from fees, grants, and other receipts amounts to £6,373; and the sum of £8,838—of which £1,454 is ear-marked for interest on loans and sinking fund—is thus left to be provided out of the municipal funds. On the permanent staff there are in all one hundred and nine teachers or other officials, eighty-four of whom devote to the school varying portions of their time—according to the duties in which they are engaged. Twenty-five officers are wholly in the service of the school.

Of inestimable value to the school is the active assistance of the Birmingham Jewellers' and Silversmiths' Association, and of other employers. To Councillor Charles Green, an ex-chairman of that Association, is due the credit of suggesting the establishment of the Vittoria Street branch school. On his proposal a special class for jewellers and silver-

smiths was opened in 1888 at the Ellen Street branch, and so successful did that class prove that in the following year the City Council sanctioned the acquisition of the building in Vittoria Street. The School of Art Committee have let to the Association, for the teaching of processes, a room in that branch school. Students are admitted to that room, called

School Sub-committee Mr. William H. Lord is chairman. The Birmingham Architectural Association is also allied with the Central School; the Midland Association of Flint Glass Manufacturers annually offer prizes to glass workers in attendance at the branch schools; the class for house painters and decorators is supported by the trade organisa-

urge young artisans to attend. There had been branch schools in the jewellery district before the establishment of the Association, and the schools had been well advertised. Now, however, that the jewellers and silversmiths have personally advised their employees to attend, the number of students every year is at least 200 more than it would otherwise be. If, in any term, as large a number of students as formerly is not in attendance from any works, enquiries are made, and it often happens that the decrease is due to the fact that the manufacturer has not taken the usual steps to urge his employees to attend. The direct monetary return from studying drawing, design and modelling, comes eventually both to employer and employed; but it must not be expected too speedily, or without care and attention on the part of the student. Some years ago there was a large increase of students in one of the classes—an increase mainly due to some published remarks as to the value of drawing and design in a local industry. Several middle-aged men joined, under the impression that in about a month they could obtain from their teacher an artistic recipe for increasing their wages without much effort on their own part; and they left, disappointed. On the other hand, a local manufacturer received from London so many orders for an article of a certain trade number that he enquired who had designed it; he found that it was designed by a young student who had studied plant drawing and design at a branch school, and readily adapted to his trade the knowledge thus acquired. The manufacturers who purchase designs from outsiders often complain that those designs are unworkmanlike; but if they would do all in their power to increase the study of drawing, modelling and design amongst their own employees, who are daily experienced in the technical requirements of their industry, they would soon find qualified designers within their own workshops. This study would immeasurably increase the value of the large and beautiful collection of objects of industrial art at the museum and art gallery; for the artisans would then be able to see for themselves in what the beauty of those objects consists, and would possess skill enough to begin to follow the best masters in their respective crafts. The essential purpose of the Municipal Schools of Art is to make workmen better workmen.

A review of the work of the last decade would be incomplete did it not record the stimulus, guidance, and encouragement afforded to the students by the examiners for local awards, and by those who have from time to time addressed the students. Amongst the examiners are Mr. J. Aumonier, R.I., the late Sir Edward Burne-Jones, Bart., Mr. Jethro A. Cossins, Mr. Walter Crane, R.I., M. E. Lanteri, Mr. W. J. Wainwright, A.R.W.S., the late M. Willms, and Professor Bertram C. A. Windle, M.A., M.D., D.Sc., B.Ch., F.R.S. Those who have delivered addresses include: The Right Hon. Joseph Chamberlain, M.P., Professor Sir W. B. Richmond, R.A., Sir Charles Robinson, F.S.A. (Crown Surveyor of Her Majesty's pictures), Mr. G. H. Boughton, R.A., Mr. Thomas Armstrong, C.B., (formerly Director for Art of the Government Department of Science and Art), the Right Hon. Sir William Hart Dyke, Bart., M.P. (then vice-president of the Committee of Council on Education), Mr. J. Thackray Bunce, Mr. W. Holman Hunt, R.W.S., the late Mr. William Morris, Mr. T. G. Jackson, R.A., and Mr. E. Onslow Ford, R.A. Mr. Wainwright, an ex-student, whose devotion to the school is only equalled by its pride in him, and who had for several years prepared for the Committee most valuable reports on the work, was in February, 1895, invited to distribute the prizes and to address the students. His eminence alike as an industrial designer and a painter justified the selection. He said that he regarded the invitation as an act of recognition from the Committee to the old students, and continued:—"Some of us are practising our art far away from the scenes of our youthful studies; others are still in the city, and of these many are here present. And I ask you, my old fellow-students and colleagues, to call

PANEL, 'THE SINGERS,' IN THE TOWN HALL, BIRMINGHAM. BY HENRY A. PAYNE

the Technical Room, on conditions jointly adopted by the committees of the School and of the Association, and intended to secure an adequate training in drawing, design and modelling; and the instruction given in it is under the control of the Association, of whose Art and Technical

tions; and Mr. Thomas Cond, Alderman Cook, and Councillor Davis, all local manufacturers, yearly give prizes. Much more could be done in this direction. It would be of great service if employers and foremen, encouraged by the success which has attended the work in Vittoria Street, would

my voice your own. And we will raise it, first, in affectionate tribute to those city fathers to whose unwearying zeal in the cause of art the community owes so much, to Mr. Alderman William Kenrick, to Mr. John Thackray Bunce, and their colleagues, past and present. Those names, so heartily received to-night, will be held in honour so long as art shall be esteemed, and unselfish devotion to public duty accounted a virtue in our midst. To them we owe the advantage of having had the early guidance of our revered master, Mr. Taylor (around whom we are gathered to-night), and who must see in all this a recognition of his labours. He has been to us a good master. Ever, by example and precept, has he shown us what it is to be an artist; and wherever our subsequent steps may have taken us, his early influence has never been effaced, and can never be forgotten."

MODERN HOSPITALS.*

By WILLIAM HENMAN, F.R.I.B.A.

THE subject of this paper is an extensive one, capable of being treated in a variety of ways and at considerable length; but it will only be possible here to make a general survey of the numerous classes of buildings employed for hospital purposes. Yet in making that survey I may be able to direct your attention to the principles of design and construction which experience has so far indicated to be essential, and to note some details which have proved serviceable, as well as to indicate the direction in which further improvements may reasonably be expected.

Several eminent authorities have written exhaustively upon the history of hospital design and development. To one of the most modern and comprehensive works, entitled "Hospitals and Asylums of the World," by Sir Henry C. Burdett, I am indebted for the facility of examination and comparison which are afforded by the large number of plans of hospital buildings therein set forth. The late Sir Douglas Galton's publication, entitled "Healthy Hospitals," also contains much valuable and fairly up-to-date information in a condensed form.

Presuming you are all more or less acquainted with the literature upon the subject, we will proceed to enquire why it is that hospitals are a necessity, and what are the principles which should guide us in their design and construction. Primarily, they are required because in many homes serious illness or accident cannot be properly attended or treated. Secondly, the larger of them form

centres for medical, surgical, and nursing instruction. The art of medicine and the science of surgery, particularly the latter, have made great strides of advancement during the last half-century, and it is impossible to bring to the bedside of all who might benefit by them the various means and appliances which science and art have devised for the alleviation of suffering or the cure of disease. Unfortunately it is the lot of many to have had experience of serious illness in their homes. Let us suppose such happens in a family consisting of several members. One of the loved ones being stricken down with disease or hurt, a room has to be set apart for the patient. Someone, may be a paid nurse, has to be in attendance, for whom another room, as sleeping apartment, may have to be given up, while someone else watches by the bedside of the patient. Those rooms must be periodically cleansed and dusted. Fires have to be kept up in cold weather. Additional work is thrown upon the kitchen, special foods and nourishment having frequently to be prepared and regularly supplied. The physician or surgeon, sometimes both or more than one of each, comes and goes and may even at times have to remain in the house and be provided for. Medicines and appliances have to be procured and administered. Members of the family may have to relinquish their ordinary avocations or recreations so as not to disturb the patient. Children must be kept quiet, and everyone moves about the house as noiselessly as possible.

Under such circumstances, is it a wonder that illnesses cause considerable inconvenience and often tax severely the capabilities of even the best arranged houses of well-to-do people? How much more then is that likely to be the case in small and badly arranged houses occupied by the families of the poor.

The foregoing words not only give reasons enough why hospitals are required, but indicate the main principles which must guide us in designing a workable hospital. I say a "workable hospital" because it is essential to realise that a hospital is not merely a ward or even a series of wards for the reception of patients. The ideal of a perfect hospital would be a building, or set of buildings, in which a number of sufferers can collectively be attended and nursed with as much safety, ease, comfort, and convenience as a single patient could be in a detached house specially designed and constructed for his particular requirements, regardless of expense.

What I have so far endeavoured to indicate is that sufferers from ill-health, accidents, or disease are more or less helpless individuals who require trained nursing under the watchful care of physicians or the skilled services of surgeons.

Comfort and quiet have to be secured in the wards; their construction and fittings must be such that they may be maintained in a clean

FINGER-PLATE, COPPER CHASED PEACOCKS.
BY W. FRENCH.

and healthy condition with the least possible labour and without inconvenience to the patients. Sanitary and ablutionary appliances must be near at hand, cautiously arranged and fitted so that neither nuisance nor danger to health can result from their proximity. A well and evenly-lighted room for surgical operations should be equipped with every useful appliance and instrument which skill has devised. Suitable day and night accommodation must be set apart for the medical and surgical staff, for the nurses, maid-servants and male attendants, and in the larger institutions for house governor, secretary, matron and other officers necessary for the management. There must also be a dispensary and space for ambulance requirements. Kitchen accommodation and appliances must be adequate, with ample space for stores of all descriptions. A well-appointed laundry is required, and there should be a decent place for the reception of the dead, with post-mortem examination room adjoining.

When a clinical school is attached to a hospital, further provision has to be made for lectures, post-mortem examinations, pathological and chemical research, also common rooms, cloak rooms, and conveniences for the use of the teaching staff and students. Additional floor area is also required in the wards around the beds when the students are numerous. Connected with most large hospitals are out-patients' departments, which, although useful and necessary in populous localities, are not essential adjuncts.

With the exception of those which are provided and maintained by medical or surgical practitioners for their own use, hospitals are public institutions erected and supported out of public moneys, by individual generosity, or by subscribed funds. In either case they should be designed and constructed with a view to true economy, not only in the first outlay upon the site, building and equipment, but also as regards the labour and expenditure daily incurred. Externally the buildings

MODELLED DESIGNS: SET OF BELL PUSHES, METAL REPOUSSÉ. BY W. MORRIS.

* A paper read at the Carpenters' Hall on March 8th, 1900.

should certainly not be mean, much less repulsive, in appearance. If small, they may be homely in character; if large, they should be dignified in their architectural treatment; but whatever style may be adopted, it should never be permitted to interfere with convenience of plan or the appropriate requirements of the buildings.

The architect must ever remember and the builder, as well as every workman, should be made to realise that, apart from the knowledge and skill of the physician or surgeon and the watchful care of nurses, there is much in the design and construction of buildings intended for hospital purposes which may either add to or detract from the comfort and chance of recovery of patients, as well as either secure or impair the health and convenience of the staff. The physician, the surgeon or the nurse who by ignorance or neglect jeopardises the life of a single patient is justly condemned; how much greater then is the responsibility of those who, having been entrusted with the design or construction of the buildings, may through acts of commission or omission endanger the health of many, or cause inconvenience and discomfort, so long as their work is permitted to exist.

Some buildings have been badly designed, others improperly constructed, adapted or added to, others inadequately maintained or cleansed, and in others the sanitary appliances and drainage are defective. Such buildings are liable, in the course of time, to become infected to such an extent that patients would often recover more quickly or with greater certainty in an ordinary dwelling.

In view of these facts, and because our soldiers during the Crimean War, when wounded or stricken with disease, made better progress towards recovery in temporary huts, and even in the open, than when nursed in permanent buildings—most of such buildings, by the way, not having been designed or properly equipped for hospital purposes—a cry is raised from time to time that all hospitals should be temporary structures which should frequently be destroyed and renewed. This however is an exaggerated idea, for there is no real reason why a properly designed and suitably constructed permanent building should not continue serviceable if adequately maintained and periodically cleansed.

Temporary buildings, if frequently destroyed and replaced by new ones, are far too expensive; the best of them will not compare in comfort and convenience with those that are of more permanent construction, and, as a matter of fact, the so-called temporary buildings are too often permitted to exist and be used long after they ought to have been destroyed. There are many occasions, no doubt, when temporary hospitals become a necessity to meet the requirements of epidemics or other emergencies, but the most reliable authorities rightly advocate that hospitals should generally be of a permanent character, carefully designed and constructed on the best known sanitary principles. It then rests with those who are responsible for their maintenance whether or no such buildings remain healthy and permanently suitable for hospital purposes, because it is a fact that, without constant care and attention to cleanliness, the bringing together under one roof of a number of persons in bad health is liable to contaminate the buildings with germs of disease, which may become a source of danger to the health of both patients and staff; consequently, one of the problems which architects are expected to solve is how best to design and construct buildings which, by ordinary means and reasonable care, may be proof against the lodgement of these injurious germs, or whatever it may be which causes an unhealthy condition of the buildings.

Although during recent years science has done much to enlighten us with regard to the propagation of disease, still there is much that remains obscure; and, although architects can only be guided by what is definitely known or generally accepted as essential, they may by personal observation and minute attention to details apply such knowledge and experience with more or less advantage to the health and comfort of those

who occupy the buildings with which they are entrusted.

The late Sir Douglas Galton, in the concluding remarks to his generally excellent treatise, entitled "Healthy Hospitals," enumerates *light, air, and warmth* as the three essentials of hospital design, but I venture to suggest that *warmth* is not always required, and prefer to substitute for it as the third essential, *purity*—for that is a constant necessity. Having before me, whilst writing, the publication to which I have just referred, my eye was attracted by the last paragraph, which seems to me somewhat unjust to architects and uncalled for. It runs thus: "It is hoped that by bringing together this information, the erection of large palatial hospitals in towns or other localities which are not suited to them will be discountenanced and that the hospital architect, instead of seeking to erect a monument of his skill and taste in architectural design, will be content to provide simple structures, abundantly supplied with light and air, in which the interests of the patients and their recovery will be not only the first, but the only consideration."

It sounds very plausible, but it is reasonable to ask why the skill of architects should be at all employed on such buildings if their art is to be ignored; for, as a matter of fact, and it would be to the advantage of all if everyone would remember, it does not follow that, because a building is architecturally pleasing it is consequently more expensive or less appropriate for its intended purposes than is one devoid of architectural merit.

It would not be difficult to point to hospital buildings, in the design and construction of which neither cost nor trouble has been spared in the endeavour to make them perfect in the interest of the patients and their recovery, the external appearance of which, to say the least, is unsightly; and yet, so far as I can learn, the patients progress no better in them than they might do in buildings less costly but designed with some degree of architectural taste.

With regard to the General Hospital, Birmingham, completed in 1897 from my designs, whatever opinions may be formed of its architectural treatment for a city hospital built and supported by voluntary contributions, it is within my knowledge that, if the external design had been stripped of every architectural feature, the material employed being terracotta, no greater sum than from £5,000 to £6,000 could have been saved. Do you suppose that the citizens of Birmingham begrudge so comparatively small a sum out of a total of £210,000 which they have provided for the site, the buildings, and their equipment?

Is there not even more than a probability that, out of the hundreds who will reside in those buildings, either as patients or those who minister to them, there may be many who will be cheered by the evidence constantly before them that, in addition to providing for their comfort and wants, thought and consideration have been bestowed upon the artistic design of the buildings in a manner to mark the nobleness of the work performed in them? At least, I know that the friends of the patients, the staff, and the general public are favourably impressed by the architectural character of the buildings, and that visitors to Birmingham, of every grade, are taken to view them among the sights of the city.

Apart from the broad treatment in architectural design of hospitals, there are minor matters of detail worthy of attention. For instance, sanitary conveniences are required throughout hospitals, therefore soil and waste pipes are a necessity and have to be provided in numerous and frequently prominent positions. In some cases they are hidden away in such a manner as to be difficult of access for inspection or repair, but more frequently nowadays it is the custom to exhibit on the exteriors of hospital buildings elaborate examples of the plumber's art; yet I venture to believe you would give preference, so far as appearance is concerned, to the inoffensive arrangement of such pipes at the General Hospital, Birmingham; and, judging from results, there is not the least reason to suppose that the unsightly exhibition of the bare bones of plumbing requisites are one whit more

serviceable, and certainly no less costly nor more easily kept in suitable repair.

Other matters of detail in which, by a little art, the common requisites of everyday hospital use might be made more sightly and even pleasing in appearance could be enlarged upon, but we must return to general principles.

In order to secure the three essentials of *light, air and purity*, it is necessary to have a suitable site, ample in extent. It should stand high and dry with an inclination preferably towards the south, and the axis of all long wards should run as near north and south as the nature of the site and surroundings will permit, and be so arranged as not to overshadow one another; by these means good light may be secured, and, although the chance of supplying fresh air from without is thereby facilitated, it is a difficult matter in our changeable climate to ensure an adequate and constant change of air within the buildings, for whatever construction may be employed as a protection from the outer elements, it must of necessity more or less impede the free movement of air which takes place in the open, by which purification of the atmosphere is to a large extent effected. It is generally recognised that air soon becomes vitiated even in buildings continuously occupied by a number of people in reasonably good health, and unless frequent change of atmosphere is by some means brought about an unhealthy condition results. In hospitals it is of still greater importance to have a constantly changing atmosphere, because contamination of the air more readily takes place around those suffering from disease or hurt.

I may again revert to this all important subject of ventilation, but will pass on now to the third essential *purity*, without the two former *light and air*. *Purity*, or in other words cleanliness and freedom from defilement, can scarcely be attained. In the manner of building frequently adopted, although wards, rooms, and corridors about a hospital may be well lighted and provision be made for continuous change of atmosphere within, there are plenty of cavities and void spaces where impurity may lurk and be little suspected. Consequently the air supply to such buildings becomes contaminated. Although it is advisable to avoid all inaccessible places where impurities may accumulate, I must warn you against an error into which some have fallen by supposing that all walls, floors and ceilings should be of hard and impervious materials. If so constructed, rooms or wards are far from being pleasant places of abode. It is more difficult to properly temper and ventilate them; condensation takes place upon the more exposed surfaces in cold weather; sounds reverberate in a distressing manner; and, being unyielding in their nature, such materials are liable to crack, and are then difficult to repair or make good. Some suppose such buildings to be fire-resisting in the highest degree, but experts demonstrate that materials more pervious have greater fire-resisting qualities.

Although advocated by many authorities, it is, to my mind, questionable whether it is advisable to coat all walls and ceilings with a non-pervious material in buildings where natural means or exhaust methods of ventilation are depended upon. Doubtless the lower portions of walls, where they are liable to become dirtied or splashed, should be coated with a washable material and be frequently wiped over. The floors also should be of non-porous material. Teak or oak boarding, tongued and grooved, grounded with paraffin wax and wax polished, makes a most comfortable, and at the same time, a most efficient flooring. It can be kept clean without having to be wetted, and is less hard, cold, and unyielding than marble terrazzo, now frequently employed. That material, however, is, perhaps, the best available for corridors, operating and similar rooms, but when employed on large surfaces its unyielding nature causes irregular cracking, which cannot be satisfactorily repaired.

Following in importance the three essentials of *light, air, and purity* come suitable temperature, cheerfulness, and quiet, all of which may be secured by care in design and construction. Other requirements are—perfect sanitary and ablutionary appliances, ample

and well distributed hot and cold water supplies, and also good artificial lighting (the electric light being preferred, because it does not contaminate the atmosphere). Provision must be made for cooking suitable food for both patients and staff; washing and laundry apparatus are necessary, and also means for distributing meals and other requisites, including lifts, when buildings are of two or more storeys, are also needed.

It being conceded that hospitals are a necessity of the times, naturally some kind of classification must be adopted. First, as regards individuals, they will be divided, men, women and children; then as regards their complaints, when the numbers to be accommodated under one roof suffice, broadly into medical and surgical, which may be subdivided into non-infectious, contagious and

In addition there may be small-pox and fever hospitals, hospitals for the treatment of paralysis, epileptics, cancer and consumption, also workhouse infirmaries and military hospitals. The following may also be classed among hospitals:—Homes for incurables, convalescent homes, homes for inebriates, idiot and lunatic asylums, and prison infirmaries. It would evidently be impossible on the present occasion to lay before you all the various differences and details necessary to be attended to in the design of these many classes of hospitals, for not only will each require special treatment, but in each case the conditions of site, its surroundings, and the number to be accommodated will greatly influence the plan and style of the buildings; yet the general principles necessary to secure healthy hospitals and the reasonable comfort

avoided by employing the Plenum system of ventilation, and by adopting an arrangement of plan such as that devised by him for the Royal Victoria Hospital, Belfast, he pointed out how facility of administration was secured, together with greater comfort to the patients and the convenience of the staff.

Correspondence.

New Street from Holborn to the Strand.

To the Editor of THE BUILDERS' JOURNAL.
SOUTHAMPTON.

SIR,—I am interested in the proposal of the "Architectural Review" to arouse the attention of the profession with regard to this

MODELLED PANEL, "BASKERVILLE." BY FRED MASON, STUDENT OF THE BIRMINGHAM MUNICIPAL SCHOOL OF ART.

infectious, serious accidents, burns and minor hurts.

Locality will also determine the number, size and character of hospitals; for small towns and villages, the cottage hospital will suffice; sparsely populated districts will combine to provide isolation hospitals for infectious diseases; but in larger towns a general hospital may be required, and in cities there may be more than one general hospital as well as hospitals for special purposes, such as orthopaedic, ophthalmic, throat and ear, skin and urinary, lying-in, women and children, dental, &c.

and convenience of both patients and staff are in all cases similar.

Mr. Henman, by means of a number of lantern slides exhibited upon a large screen, then illustrated various points in connection with hospital design and construction by plans and views, and explained the details of various sanitary appliances manufactured by Messrs. Morrison and Ingram, of Manchester, which incorporate suggestions he has made with the intention of ensuring simplicity and cleanliness; also, by plans of several recently erected large hospitals he demonstrated how the excessive length of corridor might be

undertaking of such colossal magnitude. I should like to suggest that, by way of "overture" you publish a plan (ordnance scale) marking by a red or strong line the best known extent and position of the proposed remodelling, and I feel assured the London County Council will not fall into the not unusual error in such matters of being too "cheese-paring"—this will be an occasion for doing something for that which has done nothing for us—posterity.

When the plan I have suggested is prepared I should like to have noted on the "doomed" area all buildings of historical note and architec-

tural or antiquarian interest, and I would suggest that careful sketches of all of such buildings should be preserved, and, in special cases, even models made. I have long since advocated that in order to hand down to posterity an interesting and valuable "History of England" there should be found someone in every city, town, and hamlet to keep a faithful record of all that is ancient and interesting, and if we only pause for a moment to think of the sites that have been cleared throughout the country which were formerly the homes of our greatest artists and literary men, how bitter is our regret for our callousness towards them.

WILLIAM BURROUGH HILL, F.S.I.

[We have already published a plan showing the extent and position of the proposed improvements. We commend to the London County Council our correspondent's suggestion, which strikes us as an admirable one, that an official record should be prepared of all the interesting buildings that are to disappear.—ED.]

in your columns (see p. 75 of your issue for March 7th, and p. 100 of last week's issue), I send you copy of a letter I have sent to Mr. Maurice Adams, in which I say:—

"It so happens that my letter to the 'Times' was my first attack on the Architectural Museum, as it was written before the letter which appeared in the 'British Architect' of March 2nd. I am sorry you look upon it in the nature of an attack, as my purpose was simply to call attention to the existing state of things (which I maintain are as I described them) with a view to give the museum a new life. In your letter to the 'Times' you say that 'the taste for mediæval art was for a time out of fashion.' This I am afraid is true, but why? I believe it is because the work commenced was not carried on. When Gothic was perhaps in full favour; there appeared those delightful little manuals on Gothic ornament issued by Parker, at Oxford. These were just what were wanted to stimulate interest, and at the end of the second manual I find a notice of the Architect-

become a subscriber and endeavour to get others to help. As regards Ruskin's casts, though unable to find important specimens, I am glad to hear that they are all in a satisfactory state, and hope to see them before long properly classified and hung."—Yours faithfully,
MAX JUDGE.

Ellipse by Compasses.

To the Editor of THE BUILDERS' JOURNAL.

HERSHAM ROAD, WALTON-ON-THAMES.

SIR,—I will not presume to encroach more than necessary in reply to Mr. Percival's letter in last week's issue. I fully recognise that I am bound in courtesy to your readers generally (especially to those who may be interested in the matter) to substantiate the claim made in the issue of December 6th, 1899, and since. This I can do, and with regard to Mr. Percival not being able to work out the ellipse satisfactorily, I have this proposition to make. I will take Mr. Percival's own figures—namely, major axis 3ft., minor axis 2ft.—

PRICES OF STOCK BRICKS. A MONTHLY RECORD OF THE LAST DECADE.

Price of Bricks

To the Editor of THE BUILDERS' JOURNAL.

BALHAM, S.W.

SIR,—On page 370 of your issue of January 17th I drew attention to the extraordinary reply of your expert R. W. C. on the above subject. I feel that, having made the complaint, it would be ungenerous of me to leave the question where it stands (as R. W. C. has not replied), so I submit a record of prices during the ten years asked for by the original querist (page 340, issue January 3rd last), which will, I trust, be as useful to your readers generally as to him. Monthly prices are given throughout each year, but where the prices varied within the month the average for that month is given. These prices are taken from the books of one of our principal London brick merchants and have been carefully checked by those of another. As such a mass of figures as this represents would be tedious to follow, I have adopted the more telling graphic form by which the behaviour of the market is seen at a glance. The prices given are for stocks per 1,000 "alongside" in the river in London. The price of bricks delivered to any job could be ascertained by adding for wharfage, unloading and cartage, 4s. 6d. to 6s. 6d. (or more), according to the distance from the nearest wharf. The prices of bricks obtained from other sources, such as Cowley stocks via Paddington basin, would be governed by river prices. It is worth while to note the recent great fall in the prices of bricks after three years of high prices; at this time of the year such a fall is, perhaps, unprecedented.—Yours faithfully,
J. D.

The Architectural Museum, Westminster.

To the Editor of THE BUILDERS' JOURNAL.

7, Pall Mall, W.

SIR,—With reference to the correspondence about the above museum which has appeared

in your columns (see p. 75 of your issue for March 7th, and p. 100 of last week's issue), I send you copy of a letter I have sent to Mr. Maurice Adams, in which I say:—
"It so happens that my letter to the 'Times' was my first attack on the Architectural Museum, as it was written before the letter which appeared in the 'British Architect' of March 2nd. I am sorry you look upon it in the nature of an attack, as my purpose was simply to call attention to the existing state of things (which I maintain are as I described them) with a view to give the museum a new life. In your letter to the 'Times' you say that 'the taste for mediæval art was for a time out of fashion.' This I am afraid is true, but why? I believe it is because the work commenced was not carried on. When Gothic was perhaps in full favour; there appeared those delightful little manuals on Gothic ornament issued by Parker, at Oxford. These were just what were wanted to stimulate interest, and at the end of the second manual I find a notice of the Architect-

ural Museum. Unfortunately, there is no date to the edition, but it was at the time of the museum's location at Cannon Row, and I was delighted to come across it; for, besides a few lines in Baedeker's 'London,' it is the only information I have ever been able to find in any publication. There is no mention of it in the 'Year's Art,' at least, of recent years; nothing in the Kalendar of the Institute. No wonder that subscriptions are not forthcoming, for the simple fact that most people are unaware of the existence of the museum. I was not exaggerating when I said that this museum should be to Gothic what the British Museum is to Classic. You admit that the collection of English Gothic casts has no equal; the casts are there, the thing is to let people know it, and, when they do know it, to have the contents of the museum so arranged that they may be studied. An appeal should be sent out to the architects and artists of London; to the members of the Royal Institute of British Architects as a body, and individually; and to the other architectural societies. Have they been so appealed to before for the furtherance of the study of Gothic? We want more of those manuals of Parker's, of which three made their appearance. Little pamphlets would do more good on Gothic architecture than the great works which are for ever appearing. And as to the proper arrangement and numbering of the casts a great change might be effected by voluntary help if it was applied for in the right direction. I shall be glad if this correspondence wakes people up, and I hope it will be the means of starting the museum afresh. But we must first awaken that interest for Gothic among students and workmen that undoubtedly did exist not so very long ago. I should be glad to receive a copy of the last annual report, with the present constitution and list of subscribers, and I shall only be too glad to

set out the ellipse and post it to him, if he will send me his address, on the condition that he will frankly and conscientiously report the result in your correspondence column. As to the query, "Why are eight segments of circles necessary to complete a true ellipse?" this is, I think, sufficiently seen in the figure and explained in the article of December 6th last.—Yours truly,
R. RAMM.

Royal Society of Painter Etchers.—The eighteenth exhibition of this society is pleasing, but not remarkable.

Church Building Society.—The Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels have made the following grants for new churches: Cardiff, St. Stephen, £75; Knowle, Bristol, £1,000; Notting Hill, W., £250; Calmore, near Walsall, £1,000; and Plumstead, Kent, £150. Towards re-building: St. Mary's, Nevin, Carnarvon, £60; and St. John's, Sidecup, £100.

"Giotto and the Legend of St. Francis" was the title of the Rev. John S. Carroll's recent lecture at the Glasgow Corporation Galleries. He first dealt with the frescoes attributed to Giotto in the Upper Church of St. Francis in Assisi, the birthplace of the saint. They are twenty-eight in number, and represent various scenes taken probably from the life of St. Francis by the great Doctor of the Order of Franciscans, St. Bonaventura. There was a natural fitness in Giotto thus painting the legend; for just as Francis set aside the unrealities of the theology of his day, so Giotto swept away the sombre conventionalities of Byzantine art, and painted the world more nearly as it exists. The lecturer concluded with a reference to the four great frescoes, undoubtedly by Giotto, in the vaulting over the high altar in the Lower Church at Assisi.

MEERLUST AT EERSTE RIVER.

OLD CAPE HOUSES.*

THIS book makes its appearance at a most opportune time—a time when the attention of everyone is directed to South Africa. It is not an unusual thing in history for the arts of Peace to have gained by association with War, and perhaps in this present instance the direction of attention to the subject of this work may impress a good many persons with a better idea of the many useful hints to be gained from remote quarters of the globe. One thing it should effect—the detestation of the modern corrugated-iron roofed homes in Cape Colony, which are but one instance of the many importations that have no interrelation with the country and which have been destructive of every colonial industry.

These old Colonial reed-thatched buildings at the Cape are characterised by their extreme simplicity, yet are pleasing and home-like in appearance. They are of blunt-edged plaster-work and stand with dignity within the white-walled inclosures of the country or cheek-by-jowl with the modern town warehouse. These old buildings were erected by the early Colonists—who seem to have been their own architects—of the Dutch East India Company's settlement at Table Bay, and lie within a radius of about fifty miles from Cape Town. This very fact of having been built without the aid of an architect seems to have told in their favour, for with all due deference to the architect of the present day, modern designs of domestic work are

* "Old Colonial Houses of the Cape of Good Hope." Illustrated and described by Alys Fane Trotter; with a chapter on "The Origin of Old Cape Architecture," by Herbert Baker, A.R.I.B.A. London: B. T. Batsford, 94, High Holborn, W.C. 10s. 6d. nett.

largely of a most excrescent kind, tawdry, overlaboured, self-conscious, and inharmonious with either the inhabitants or the surroundings. And these characteristics seem about to be carried with our boasted civilisation into countries where a style of architecture exists which is traditional and is suited to the needs and climate of the country. What a contrast is it to see how these old Dutch settlers, carrying their preconceived ideas and traditions into a new and 'strange' country, have modified their notions and forms of construction under the influence of climate, country and needs into a new and artistic style, seemingly made specially for South Africa.

The authoress, Miss Alys Fane Trotter, has produced a most interesting, well-written and useful work, and her efforts have been enhanced by the liberal and astute publisher, Mr. B. T. Batsford, who is now so well-known for his publications affecting the architectural and engineering professions and building trades. The illustrations—some twenty-six crayon and pencil drawings by the authoress and eight photographic reproductions—are excellent, and well express the great charm these buildings possess with their white sun-scorched and sun-gilded walls, surrounded by the everlasting hills, and cannot fail to suggest to the architect many hints of treatment that might be adapted to this country. An able and interesting chapter on the origin of Cape architecture is contributed by Mr. Herbert Baker, A.R.I.B.A., the architect of the Rt. Hon. Cecil J. Rhodes's house, "Groote Schuur," a remarkable and most beautiful design in the same style as the old settlers' buildings; in fact, Mr. Baker in this house gives us an example of what can be done by refined and traditional treatment in a style adapted to the country—worthy of emulation by all his fellows, both in Cape Colony and in this country.

Little is known about the actual building of the houses; slave labour was employed, this being imported from Madagascar. Teak and ebony were brought from the Dutch Company's possessions in India, and in the furniture and woodwork colonial products, stinkwood, yellowwood and ironwood, were also used. Bricks and tiles were then made at the Cape, it was also the custom of the Dutch Company to send bricks and tiles from Holland to their various settlements, and these are doubtless the small red bricks still found in good preservation and mentioned in the Diary of the Company as "Amsterdam bricks."

There is no exact prototype of the spacious colonial homestead, either in the small, low, tile-roofed sheds of the Holland marshes, or in the many-storied, narrow-fronted houses of the cities. In these colonial dwellings there is to be

found a large hall and a broad "stoep," or raised platform, surrounding the house, adapted for primitive life and open hospitality. The two plans on this page (Figs. 1 and 2) are almost universal in larger Cape houses; Fig. 1 shows the form most common in the Cape Peninsula, where suitable materials could more readily be obtained for building the back part of the hall with a flat roof; Fig. 2 shows the form which prevails beyond the Peninsula. It is the gable, the most distinctive feature, that must be looked to when comparing the architecture of Holland and the Cape. Here we find that distinctive feature of Dutch architecture, the curling scroll, but at the Cape it becomes much more bold and simple, due doubtless in great part to the material and economy of labour, and is much preferable to the distressing finical and rococo prototype. For this comparison Belgium must be looked to as well as Holland. The Cape gables seem to be of general types, of which Fig. 3 is an example. This has as its most distinctive feature two vertical bordering lines, with spreading scrolls at the side. This form is undoubtedly adapted from the gable which nearly every eighteenth-century house in Amsterdam possessed. The Amsterdam houses had no basements owing to their being built in wet mud, and therefore the roofs were used as storage lofts. The gable surrounding the doors to these lofts was carried up in brick, with a stone pediment and side scrolls; the vertical lines formed by the edge of the brickwork represent walls which run back into the roof behind the scroll, forming an ornamental buttress. A few instances of this gable are to be found in Cape Town, but plaster here takes the place of brick and stone. In the country this scroll

FIG. 1.—TYPE IN CAPE PENINSULA.

FIG. 2.—TYPE OF COUNTRY HOUSE.

widens out into a wall screen to cover the spreading thatched roof behind, but the now meaningless vertical lines still remain; a true gable is thus formed, as distinct from a loft-door dormer. If we eliminate the conditions under which the Flemish merchant built his house, with its great height, its many windows and its narrow front, and replace his conditions of life by those of the Colonist, with his simpler standards and at his disposal unlimited ground space, the Cape houses will not be found dissimilar.

It is an interesting fact that though the form of gable with square projections and no moulding (asin "Meerlust," illustrated on the previous page) is seldom seen in Holland or Belgium it is very common on the south-east coast of England in the brick cottages and farm-houses, the building of which is attributed to Flemish refugees. There is another kind of gable with pilasters and other classic features and ornaments that occurs frequently in the districts settled by the Huguenots, and this seems to associate these gables with French influence. There appears to have been an eastern influence in some of the old Cape work, such as the panelled and louvred screens that divide the long halls, due probably to the Malay slaves in the service of the company.

"Meerlust," illustrated on the previous page, is one of the largest and most ornamented of the farms. The numerous sheds and out-buildings are covered with plaster ornament. The house has two halls, and the front has been rebuilt. The flooring is of square red tiles, small red bricks and teak.

The early casement with transoms and lead glazing, so characteristic of the Netherlands, is not to be found at the Cape, but is replaced there by tall wooden-barred small-paned sash windows; this seems to point to the settlers having taken with them the latest invention—so establishing a precedent—while the older forms died slowly at home.

It seems somewhat strange, though frequently occurring in other countries, that, although doing so well in simple domestic work, when a monumental piece of work was attempted the builders should have failed so ignominiously as in the Town Hall at Cape

MEERLUST HEN HOUSE.

Town; it is a great contrast to go from this Town Hall to the noble and bold wall of the river at Elsenburg, or the basin of the Swimming Bath at Constantia.

D.

Under Discussion.

History and Art—a Florentine Outline.

With this as his title, Mr. James A. Morris, F.R.I.B.A., before last Wednesday's meeting of the architectural section of the Glasgow Philosophical Society, began by elucidating the statement that as heredity in the human family indicated weakness or strength of individual character, so the history of a nation to a certain extent illustrated its art. This was very well brought out in connection with Italian art, where the crowning glory belonged to the Tuscan, which was the mother and sweet matron of all art, and which specially flourished in Florence, the fair city of lilies. Treating of the history of art, he pointed out that it might be safely taken that from the time of Cimabue to the close of the sixteenth century there was little or no divorce between the arts; and proceeded to contend that just as it was as true to-day as ever it was that "life was more than meat and the body than raiment," so it was their duty to know and understand the life and the needs of our own day and the wants of our fellow men, and knowing these and knowing also our art, he urged them not to be afraid to go forward though none else followed. The lecture was illustrated by lime-light views of Florence and Florentine art. The annual meeting of the section was afterwards held, when office-bearers were appointed as follows: President, A. Lindsay Miller, architect; vice-presidents, James Chalmers, I.A. (architect) and W. D.

Horne (decorator); hon secretary, Ninian Macwhannell, I.A. (architect), 58, West Regent Street, Glasgow; hon. treasurer, William Howatt, I.M. (measurer), 146, Buchanan Street Glasgow, together with a Council.

Fifteenth Century English Architecture.

Mr. C. M. Hadfield, A.R.I.B.A., read a paper on "Architecture of the Fifteenth Century and the Early Tudor Period" before the Sheffield Society of Architects and Surveyors last week. He said the epoch of English national architecture, which flourished and developed for some four hundred years, came to an end in the midst of the sixteenth century. Its further progress was curtailed by the Renaissance, from the advent of which movement the practice of architecture as carried on at the present day commenced. The methods and ideas of the Renaissance prevailed unquestioned down to the present century, in the course of which strenuous efforts had been made to make architecture once more an original and progressive art. These efforts had to a great extent proved abortive, accomplishing only a mere succession of revivals or fashions, with the ultimate result that at the end of the century we found ourselves reverting to the so-called "classic" traditions which were in vogue at its commencement. The persistent study of our native architecture, and fidelity to its teachings and methods, were the only means of making architecture once more progressive. The work of the fifteenth century represented the latest and most fully-developed phase of English structural art. It was distinctively English, and solved all the essential requirements of a civilised and cultured state of society. It took its place unquestioned at the head of the art of its day, marking out the bounds of their work to designer and craftsman alike. Mr. Hadfield dealt with the history of the rebuilding of Gloucester Cathedral, and with the erection of the celebrated nave of Winchester, by William of Wykeham, as showing the gradual and continuous development of architecture during the period. He described King's College, Cambridge, as a classic monument of English art, and reviewed various examples of ecclesiastical work, calling attention also to the high level of all-round craftsmanship attained. In describing the domestic architecture, he took examples from the collegiate work of Oxford and Cambridge, Hampton Court Palace, &c., and traced the origin of the type of an English public hall or interior to the same period. In conclusion, he

urged on those who had devoted their life's work to the production of buildings to apply the knowledge gained by the studies and researches of the last hundred years in the light of the principles embodied, remembering the proud past of English architecture and striving to resume the broken continuity with the days when their craft represented the progress and commemorated the achievements of the English race.

Scotch Ecclesiastical Architecture.

Following up his series of lectures on "The Ecclesiastical Architecture of Scotland from the Twelfth to the Sixteenth Century" (reports of which will be found in our two preceding issues), Mr. Thomas Ross, in his fifth discourse, referred to Dunblane Cathedral as a building well preserved, and, being of one age, it possessed a unity of style not often found in our large churches. It was remarkable in Scotland for the remains of its woodwork, its stalls being almost the most complete remnants of ecclesiastical furniture. The collegiate church of Rosslyn had been quite misunderstood. Some said it was built by

Spaniards, and others that it was Scottish work, but, making a minute examination, it was shown that almost every individual detail could be referred back to some Scottish church or castle. It was this period, coinciding in a general way with the reign of the Stuart Kings, which formed what might be called the strictly Scottish period, when, through the infusion of ideas from the castle, Scottish ecclesiastical architecture assumed a national character. The founding of large monasteries had now almost ceased and collegiate churches were taking their place. These churches were small compared with the cathedrals and abbeys, and the favourite plan was a cross with aisles, with a low central or western tower, of which fine examples exist at Dunglass, Crichton, Seton, Whitekirk, St. Monans, Tullibardine, Biggar, Corstorphine, Dysart, and elsewhere. Apical ends were frequent, but unlike those of Norman times (which were circular on plan) were composed of a part of a polygon. At the opening of his sixth and concluding lecture Mr. Ross said that the cathedral of Dunkeld and the abbey of Paisley bore a considerable resemblance to each other, but while Dunkeld stood in a glorious situation on the banks of the sparkling Tay, Paisley Abbey stood on the foul and muddy Cart, and was in part used as a store for bottling ale and stronger liquors. Founded about 1163, the abbey was burnt by the English in 1307. Its principal restorer, Abbot Thomas Tervas, raised the money in part by selling wine within the monastery, a custom, as they had seen, well kept up. The whole of the west front, which was very majestic, very noble and dignified, represented between its lower and upper parts a period of about two hundred years. In the interior there was great complication and confusion in joining the later with the older work at the west wall. The Chapel of St. Mirren on the south side of the nave was a charming example of the architecture of the period. It was not possible to say how much of the monastery buildings remained, but that they were pretty well represented by the present buildings was, he thought, probable. The church of St. Giles, Edinburgh, well illustrated the growth of our mediæval buildings. What it originally was like we could not tell, but within what might be called historic times we could trace its rise from a comparatively simple, low-roofed, three-aisled building to a lofty and many-aisled church. It was the widest of all the Scottish churches, and was remarkable in this respect, that every part of its vast area had been at some period stone vaulted. Its best known feature was the tower, with its crown-like spire. Certain other towers of the same class had all perished, except that at the west end of King's College, Aberdeen, and there was rather a fine tower of the kind which belonged to the old Tolbooth of Glasgow, still standing, where everything else was changed, at the corner of High Street and the Trongate. It might almost be claimed that this form of lantern tower was of Scottish origin, or, at all events, that it reached its fullest development in Scotland. Although he had frequently given credit to certain buildings on account of their size, even the largest of the Scotch cathedrals and abbeys were small when compared with those of England and of foreign countries, but when we considered that no building had been erected since on such a scale of magnificence and thoroughness as the great Scotch cathedrals with their palaces, and the abbeys with their wide extended courts, there was no reason to be ashamed of what Scotland did during those great ages. Turning to a building of very small size, he regarded the chancel of Lincluden as a perfect specimen of genuine Gothic architecture. There was hardly in all Scotland anything more impressive than this little fragment. In conclusion, the lecturer said they had seen that the style of architecture during the period under review was imported, in all probability from England, that it was round-arched in its construction, and that the building activity was great, so great in the supply of small parish churches that it sufficed for the wants of the country for many generations. He had tried to show how the round-arched style

of the twelfth century grew in the following years into the Gothic style; that on towards the end of the thirteenth century the architecture of England and Scotland was on the same lines; that a breach occurred for about one hundred years, and that when the building of churches began again with the advent of the Stuart Kings up to the Reformation, there was a style of architecture practised in Scotland which was peculiar to it, having distinctly national features. Probably the great abbeys and cathedrals round which all that was best in Scottish public life centred for four hundred years were not the least of the great inheritances which had come down from the middle ages.

An Apology for St. Paul's Cathedral.

Canon Scott Holland delivered a lecture with this title before the Birmingham Ruskin Society on March 14th. The story of St. Paul's was simply the story of a succession of churches which had risen (the first one in 604) and been destroyed and risen again on the same space. With regard to the present cathedral, the lecturer pleaded that if they wished to examine its style and see its beauty they must not go with a mind trained in Gothic beauties, because they would be hopelessly repelled. St. Paul's aimed at exactly the opposite. What was aimed at was space; it aimed at giving a sense of brooding calm, not springing grace, so that mere proportion of space should tell on the imagination. If they looked at what it offered they would find out its beauties, but if they looked for the beauties which they found in Westminster Abbey they would not get them. Wren lived during the whole of the time in which it was built. There again was an intense contrast with a Gothic building. The Gothic building grew, and one never knew who built it; whereas on St. Paul's there was one mind who determined the fashion and shape of every single stone of the building. It had the impress of a master mind and genius. St. Paul's had no particular charm in its decoration, nor depended upon colour. Wren certainly meant it to be coloured, for he left parts of the building simply stucco on brick, but he was prevented from carrying out his wish. Their aim should be, he said, to present in the cathedral a perfect service, and the building should be made beautiful as the country's thanksgiving to God.

French Gothic Sculpture.

"The Sculpture of the French Gothic Cathedrals" was dealt with by Professor Baldwin Brown, M.A., at a meeting of the Edinburgh Architectural Society on March 14th. At the outset he mentioned the superiority of the French western façades and frontal entrances to those of England or Italy. In Germany the western façade was usually occupied by the apse, and the doorways were accorded less prominent positions. In the French examples the doorways usually possessed deep ingoos ornamented with figures in profusion, and had an inviting aspect. In English mediæval work little sculptured work was expended on the façades of the cathedrals, but was to be found only in tombs and monuments. Professor Brown, with the help of lime-light views, gave a sketch of the origin and development of the columned and figured frontal. Some views of semi-classical examples in the south of France were also exhibited. At Chartres Cathedral, erected about 1130 or 1140, the doorways were treated more timidly, and a shallower ingo than in the later examples. The statues were worked on the faces of the columns, and were supported upon small corbels. This treatment gave the appearance of suspension and insufficient support to the figures. The statues and reliefs of the cathedrals of Amiens and Rheims, which were built during the first half of the thirteenth century, were very fine, but were not so interesting as the earlier sculpture work, such as was to be found at Chartres. The tympana over the doorways usually possessed some very interesting sculpture work; a favourite subject for this position was the scene of the Last Judg-

ment. During the latter half of the thirteenth century there appeared a decline in the quality of the sculpture work.

Recent Excavations in Greece.

Mr. Charles Waldstein, Litt. Doc., Ph.D., L.H.D., Slade Professor of Fine Art at Cambridge University, gave his third and concluding lecture on "Recent Excavations at the Argive Heraeum in Greece" at the Royal Institution last Thursday afternoon. Summarising shortly the previous lectures he has given, he outlined the development of Hellenic civilisation and art and emphasised the fact that to the Greeks the world owed the picture and the statue, besides the drama, the poem, philosophy and science. They gave us the picture and the statue not as serving mere ancillary functions of decoration, &c., but as made for their own sake alone, without question of use or ultimate purpose. Phidias was the greatest sculptor of the Greeks; he was the culminating point of the whole great national system and movement. But besides Phidias we had another great sculptor, Polyclitus, of Argos, who lived from about 460 B.C. to 410 B.C. Going on to compare the characteristics of Polyclitus with those of his older contemporary Phidias, the lecturer quoted Quintilian's criticism that the former displayed great finish and feeling for formal beauty, but was wanting in the spiritual grandeur of thought found in the latter. Illustrating next the square and massive canon of proportions adopted by Polyclitus, and contrasting his style with that of some later sculptors, the lecturer gave some particulars of the famous statue of Hera by this sculptor at the Argive Heraeum—a huge figure of gold and ivory seated on a throne. An idea of its appearance was obtained from Argive coins, and many attempts had been made at its identification, but he claimed that he had had the good luck to find in the British Museum a figure previously considered to be a bust of Apollo, which, though of late Roman date, was a distinct and definite reproduction of that type of Hera, and when viewed in profile was almost identical with a head on an Argive coin illustrated at the lecture. Dr. Waldstein then discussed the sculptures that formed the decorations of the second temple at the Argive Heraeum, and illustrated his remarks with lantern illustrations of the architectural fragments which he had excavated there. In these he thought it obvious that we had the art of Polyclitus, whose relation to the Heraeum was the same as that of Phidias to the Parthenon. Some of the architectural work was unsurpassed in delicacy and finish of modelling by any piece in the Parthenon, and as a proof of the naturalistic truth exhibited in the sculpture he mentioned that in one of the torsi he discovered a muscle which his anatomical friends pronounced an anomaly but which had since been found to be developed in professional athletes. Contrary to what seemed to be implied by the description given by Pausanias, he argued that the temple must have had pedimental figures, and, showing several well-preserved heads both from the pediments and the metopes, he maintained that the art possessed the characteristics of Polyclitan style and was not Attic, as had been suggested by Professor Furtwängler. Finally, he showed a head which, whether it was of Hera or not, he thought was the best preserved specimen of fifth century art that had come down to us.

The Opening of the Paris Exhibition is stated to have been fixed for April 15th.

A new Fire Station at Wednesbury has been built at a cost of £2,150. An isolation hospital has also been built in Dangerfield Lane at a cost of £1,315.

All Saints' Church, Blackrock, Dublin.—Two memorial windows, a brass inscription, and brass communion rails have been erected in this church to the memory of the late Canon Stokes. The work has been executed to the design of Francis Robert Davies, K.J.J., F.R.H.S., M.R.I.A., by Messrs. Heaton, Butler, and Baines, of 14, Garrick Street, London, W.C.

R.I.B.A.

ANCIENT LIGHTS.

A MEETING of the Royal Institute of British Architects was held on Monday evening last, when the president (Mr. William Emerson) occupied the chair. After the minutes of the special general meetings held on March 5th had been read and confirmed, three papers on "Ancient Lights," by Mr. J. Fletcher Moulton, Q.C., M.P., F.R.S., Mr. J. Douglass Mathews, and Mr. Beresford Pite were read.

Mr. Moulton's Paper.

In the first place, said Mr. Fletcher Moulton, it is desirable to express clearly what is the measure of an owner's right in respect of ancient lights. The Prescription Act provides: "When the access and use of light to and for any dwelling-house, workshop, or other building shall have been actually enjoyed therewith for the full period of twenty years without interruption, the right thereto shall be deemed absolute and indefeasible." It is, therefore, very clear that in order to measure the light to a continuance of which the owner is entitled, one has only to measure the light actually enjoyed during the twenty years' term. Nothing could be simpler or more definite than this rule. But acting under cover of the doctrine that the law does not heed trifling invasions of right, the Courts had in practice treated plaintiffs as though they were only entitled to a reasonable enjoyment of light, no matter how complete their enjoyment in fact had been, and it had come to be considered that reasonable requirements were satisfied if the owner of the privileged windows got an uninterrupted view of forty-five degrees of sky from the zenith. Thus the question whether the encroachment is to be taken seriously or not is a very real and possibly troublesome question, even in a case where considerable encroachment may have been actually made. Mr. Moulton then went on to suggest the lines upon which it seemed to him their new legislation should proceed. An end should be put to the technical rule that damages cannot be given for a threatened injury of this kind. The High Court might safely be given the fullest discretionary power, in every case where an injunction to restrain the darkening of ancient lights can be granted, to substitute for the injunction, in whole or in part, a money payment by way of damages, so that, if the merits of the case demanded it, there would be no difficulty about authorising a definite encroachment upon equitable terms, while at the same time restraining some further threatened encroachment by an injunction. In any proposed change of the law power should be preserved to the Court to keep the rights of the easement owner intact, and to protect them as amply as at the present time by injunction. Mr. Moulton anticipated that a detail of the remedy suggested might incur the censure of lawyers, namely, that features of the building design, such as the use of white bricks, which tend to minimise the inconvenience, should be taken into account in adjudicating upon the relief. Though the suggestion had been scouted by judges, and the arguments against it were cogent, yet legislation might do much to alter the conditions so as to favour the use of white bricks. Even if allowed to become soiled they improve the lighting of closely built-in areas, and the law should encourage their use. The sooner the plaintiff brings his action to trial the better. An injunction cannot issue too early, if it is to issue at all. But there need be no hurry about assessing damages. Although the proposal took the shape of a legal reform, the question at bottom was not so much a legal as a practical question; the legal difficulties would be easily surmounted if a practically

useful way of estimating damage, and of distinguishing the easement owner's essential interests from his merely technical rights, could be arrived at.

Mr. Mathew's Paper.

Mr. J. Douglass Mathews proposed to confine himself to the difficulties experienced by architects in erecting or altering a building dominated by ancient lights, and the unsatisfactory methods now adopted to settle differences. He contended that if certain simple rules could be laid down, such as that no erection should be permitted above a line drawn at an angle of 45deg. from the horizon from the sill of an existing window, or within certain angles laterally, there would be no greater difficulty in complying with them than with Building Acts or sanitary by-laws. As matters stood, an unscrupulous person had an opportunity of preventing his neighbours from using their property to the best advantage, except by payment of compensation (often blackmail), and the law afforded no means except by mutual agreement to alter old lights in a way beneficial alike to the owner of the dominant light and to the person erecting his new building. Since the passing of the Prescription Act, nearly seventy years ago, such vast changes had taken place that what was a reasonable law then had now become arbitrary and the fair use of valuable property was interfered with. A new Act was therefore called for. New legislation, whilst carefully guarding the rights of ancient lights, should treat them more in the nature of easements and, provided that an equivalent be given, the particular merits of the case should be taken into account, rather than the hard and fast rules of law. Mr. Mathews gave it as his opinion that the proposals of the Science Committee of 1893 (see R.I.B.A. "Proceedings" for March 22nd, 1888) would be found practicable with certain alterations and conditions, one of which should be that before a building is taken down or any alteration made in an old one it must be measured, and plans, elevations, and sections drawn, which should be verified and certified by the district surveyor in London, or by the borough or other public surveyor elsewhere; and that such drawings should be available for inspection by interested parties on payment of a small fee. By this means no doubts would arise as to the extent and height of the original building, the settlement of differences would be expedited, much expense saved, fairness and equity would be secured to dominants and servients alike, and the risks and expenses incurred in stopping the progress of works, and in altering and pulling down buildings when erected, would be avoided. He hoped the Council would at once take steps to obtain an alteration in the law. As the Surveyors' Institution was as much interested in the question as the Institute, the co-operation of that body should be invited, and a Bill drafted.

Mr. Pite's Paper.

Mr. Beresford Pite first considered the restrictions on the height of buildings contained in the London Building Act, sections 15, 41, 47, 48, and 49. Briefly, the restrictions are as follows: (1) A general regulation of the height of the back of houses to ensure an angle of forty-five degrees of light. (2) An extreme limit of 50ft. in height in all buildings. (3) In streets laid out subsequent to 1862, of a less width than 50ft., a restriction of height to width ensuring an angle of forty-five degrees of light; and (4) A right of appeal granted to owners within 100yds. distance against any consent to exceptions to these limits granted by the London County Council. Though this legislation has limited the freedom of building owners, the freedom of adjoining owners to interfere has been left unfettered. Therefore, with restriction of height, might there not have been secured absolute permission to build up to that height? The author next considered restrictions of height which are not statutory, and not exercised on behalf of the sanitary interests of the community. They are the private and personal rights to preservation of access of light, when once conferred by prescription,

over the land and buildings of adjoining neighbours. These rights once acquired are indefeasible, and are superior to the statutory law, the limited height granted in the interests of the community being restrained and denied by the prescriptive right of the individual. The communal desirability of sanitary regulation in building heights is admitted; but no common or public interests are furthered by the prescriptive right of restraint. Its existence is inimical to municipal improvement, and unworthy of retention. The use that is made of claims for rights of light for delaying building operations in order to extract heavy compensation has become a serious abuse. A seldom-used window acquires an unlimited fictitious value if it is in a position to control, by delaying until a trial in court can take place, any part of an important new building. A question first suggested is whether the abolition of the private right of restriction is equitable; and, secondly, whether it is practicable. In discussing the equitableness of its complete abolition, the author referred to the general safeguards provided by statutory regulation, and enumerated various exceptions existing by waiver or covenant upon the right by prescription, as tending to show that such conditions are not unduly harsh or restrictive, nor is the property subject to them affected in value. A natural alternative to restriction or depreciation of the right to build, and one usually to be economically effected, is the simple expedient of enlarging the window or means of lighting the obstructed tenement. In discussing the possibilities of statutory reform, Mr. Pite referred to French, Swedish, and Scotch law upon the matter, observing that any of those systems—the French of no property at all in light over another's land, the Swedish of registered agreement of any such charge of right of light, or the Scotch of the recognition of a right of light where the grant by consent or implication can be proved, but denying acquisition by prescription—would be an ideal worthy of sustained effort. Two reforms advocated by the Science Committee, namely, (1) of relief from impending dominant lights by a technical obstruction, and (2) of procedure by removal from the courts to three surveyors for award of all complaints, were, Mr. Pite considered, open to the objection that, as legislation is required to effect them, it would be better to seek a more drastic method of dealing with the whole law of ancient lights, which Parliament could as easily accomplish, and which probably would avoid the necessity of any reform of procedure. The first suggestion would provide a new element of complication and conflict of doubtful advantage, the non-repeal of the Prescription Act in its application to lights ensuring a still ample field for conflict. By the second suggestion this conflict was to be removed from the courts of law to a tribunal of surveyors. Were surveyors competent to try facts which must depend on the testimony of witnesses—title, history, user, and the new technical obstruction, its fact, title, and history, all having to be proved by evidence before the simpler technical matters could be reached? As the possibility of remedy by legislation seemed remote, something might be done apart from appealing to Parliament. The removal of some of the uncertainties and want of harmony in the decisions might be secured by the gradual recognition and establishment as a precedent of a readily applied system of measurement of obstruction; this would prevent many unreasonable claims and deter claimants whose professional advisers could readily apply an accepted and customary rule to each case.

Money damages for obstruction of light should be for proved damage, and *pro rata* diminution of rental, market, or other value, or for increased cost of lighting. The effect of requiring proof of actual damage, of awarding money compensation, and of refusing to delay by injunction, except in special cases, would be to deprive claimants of improper gain through delaying building operations, and afford, on proof at trial, proper compensation, the amount of which would bear relation to the injury done.—A discussion followed.

Experimental Bacterial Treatment of the London Sewage.

AS the result of the report of the Massachusetts State Board of Health about seven years ago, experiments were made in this country with regard to the bacterial treatment of sewage, and on Thursday evening last, at the Sanitary Institute, Margaret Street, W., Professor Frank Clowes, D.Sc. (Lond.), F.I.C., gave the general conclusions derived from the experimental bacterial treatment of raw sewage in coke beds at the outfalls of the London sewage into the Thames. Professor Ramsay took the chair.

The results obtained were as follows:—

(1) The sewage was allowed to flow into large tanks which contained fragments of coke about the size of walnuts. As soon as the level of the liquid had reached the upper surface of the coke bed, its further inflow was stopped, and it was allowed to remain in contact with the bacteria coke surface for about three hours. It was then allowed to flow slowly away from the bottom of the coke bed. This out-flowing liquid constituted the "sewage-effluent." After an interval of about seven hours, the processes of emptying and filling the coke bed were repeated with a fresh portion of sewage. The coke bed was usually filled in this way twice in every twenty-four hours. (2) A purifying action was produced by the coke bed. This depends upon the introduction of bacteria from the sewage, and the maintenance of the purifying action is secured by the continuous presence of bacteria or their enzymes upon the coke surfaces, and by the frequently renewed contact of these surfaces with oxygen. (3) The aeration of even the lowest portions of a deep coke bed (see table) seems to be satisfactory in the above method of working, since the air present in the interstices of the coke between two fillings with sewage usually contains 75 per cent. of the amount of oxygen present in the air. (4) Raw sewage, which had been deprived of its larger particles by screening it through coarse gratings, lost practically the whole of its suspended matter by remaining in such a coke bacteria bed for two or three hours. It appears that the suspended particles of fecal matter undergo liquefaction by the bacteria, and do not collect upon the surface of the coke. (5) The sand and grit and finer mud, arising mainly from the wear of road surfaces, however, were deposited upon the coke surfaces, and gradually reduced the capacity of the coke bed. (6) Hair, fibrous matter, and woody fibre, derived from the wear of wooden street pavements, and particles of chaff and straw, mainly derived from the dejecta of horses employed in the street traffic, are also deposited upon the coke surfaces, and

gradually choke the coke bed. These substances, which consist mainly of cellulose, are apparently only acted upon by bacteria with extreme slowness under the above conditions. They arrive, however, in a water-logged condition and rapidly settle down from the sewage if its rate of flow is reduced. (7) In dealing with the sewage of the metropolis, it seems best to allow the roughly-screened raw sewage to undergo a somewhat rapid process of sedimentation, in order to allow these matters (5, 6) to subside; and then to pass the sewage direct into the coke beds. The dissolved matters and the small amount of suspended matters which are still present in the sewage are then readily dealt with by the bacteria of the coke bed and practically no choking of the bed occurs. (8) The sewage effluent from the coke bed is entirely free from offensive odour, and remains inoffensive and odourless even after it has been kept for a month. It is clear, except during heavy rain, when a turbidity is produced by fine mud particles. Many pond and river fish have been kept in this constantly renewed effluent for a month, and were found to be perfectly healthy at the end of that period. (9) The chemical character of this effluent may be briefly indicated by stating that on an average 51.3 per cent. of the dissolved matter of the original sewage, which is oxidizable by permanganate, has been removed by the bacteria, and that the portion which has been removed is evidently the matter which would become rapidly offensive and would rapidly lead to deaeration of the river water if it were allowed to pass into the river. The above percentage removal (51.3) was effected by coke beds varying from 4ft. to 6ft. in depth. A similar bed, 13ft. in depth, has proved more efficient, and has for some time produced a percentage purification of 64 per cent., while an old bed, 6ft. in depth, has given a percentage purification of 86 per cent. A repetition of the treatment of the effluent in a second similar coke bed has produced an additional purification of 19.3 per cent., giving a total purification of 70.6 per cent. It should be noted that the above purification is reckoned on the dissolved impurity of the sewage: the suspended solid matter is not taken into account. (10) The bacteriological condition of the effluent corresponds in the main with that of the raw sewage. The total number of bacteria undergoes some reduction in the coke beds, but the different kinds of bacteria which were present in the sewage are still represented in the effluent. (11) The introduction of such a sewage effluent into the Lower Thames appears to be unobjectionable. The river water at this part is uniformly muddy; it is always brackish and frequently salt to taste, owing to the presence of tidal sea-water. It is, therefore, not capable of being used for drinking purposes. The effluent will certainly cause no deposit

upon the river-bed, and will ordinarily tend to render the muddy river water more clear by mixing with it. No offensive smell can be emitted by the effluent as it is discharged, and the bacteria which it contains will slowly and inoffensively remove the remaining dissolved organic matter from the effluent after it has been introduced into the river. The effluent will be suitable for the maintenance in the river of healthy fish-life.

A discussion followed, in which Dr. Rideal, Mr. Collins, Mr. Dibdin, Mr. Archibald, Mr. Osborne Smith, Mr. Ackerman, Mr. Dennis, and Professor Ramsay took part, and, in reply to questions, Dr. Clowes stated that chemical productions were often present in quantity in the Thames, but they did not influence the treatment materially. They had found that rapid sedimentation did not check the process, soap and grease did not interfere with the beds, neither did sunshine (which killed bacteria), because the liquid was opaque enough to prevent the rays penetrating more than a few inches. The matter of the manurial value of the sludge did not come within their province, and the quantity of the London sewage was too great to put on the land.

THE ROUBAIX PROCESS OF SEWAGE DISPOSAL.

THE chairman (Mr. R. Johnson), the deputy-chairman (Mr. J. T. Riddiough), and the engineer (Mr. J. Garfield) of the Bradford Sewage Committee paid a visit some time ago to Roubaix, France, for the purpose of inspecting a system of treating wool-combing suds in use in that place. On the occasion of the visit the committee had the opportunity not only of seeing the Roubaix sewage treatment in operation, but also the experimental treatment of a large quantity of the Bradford sewage, which had been conveyed to Roubaix for the purpose. The sewage of Roubaix is very nearly of the same nature as that of Bradford, and when it was reported that Roubaix and Tourcoing had discovered a method of dealing with their sewage in a manner not only efficient, but calculated to produce a considerable profit, derived from the recovery of the grease from the sludge, a deputation was appointed to visit and report upon the scheme. The apparatus by which this object is effected is the invention of a local woolcomber, M. Jules Delattre. The principle underlying the method is simple. The sludge is first treated in precipitating tanks with sulphuric acid, and the grease is then washed from the sludge thus obtained with benzine, which is subsequently recondensed. The sludge, deprived of its grease, is saleable as manure, and according to statistics which are set out in detail, the cost of the treatment of 4,868,000 gallons was £42 0s. 10d., and the receipts were:—From grease, 12 tons, saleable at £4 per ton, £48; and fertiliser, 29 tons, saleable at 8s. per ton, £11 12s.—total, £59 12s. There was thus a gross profit of £17 11s. 2d., equal to a profit or £81 a day on the estimated daily flow of the Roubaix and Tourcoing sewage. The management expenses, interest, and depreciation are not taken into account in the calculation. During the visit, some twenty-five tons of Bradford sludge were passed through M. Delattre's apparatus. Twenty-two and a half tons, after the addition of a little sulphuric acid to set free the saponified grease, were passed through the apparatus in twenty-eight hours, and from it were recovered 5½cwt. of grease containing 11 per cent. of foreign matter, and 15½cwt. of filter press cake containing 27 per cent. of moisture. The grease was valued at £9 a ton on the spot. M. Delattre said the extraction of grease from such a watery sludge would not pay, and that it would be necessary to reduce the bulk to about one-fifth in the process of precipitation. The method of grease recovery invented by M. Delattre can only be applied economically to a very dense sludge. If ferric sulphate is to be used for the precipitation of the sewage (says the report), it would be necessary to adopt

Relative Impurity as Estimated by Permanganate.

		Percentage of purification calculated on clear raw sewage.
Raw sewage deprived of its suspended matter ...	3.696	—
Effluent from chemical treatment ...	3.070	16.9
Effluent from single bacterial treatment ...	1.799	51.3

River water, low tide...	0.429	—

Experimental Proof of Aeration of Deep Coke Beds at Crossness.

Samples of air were drawn off from the interstices of the coke at varying depths from the surface of the coke bed and at varying intervals after the outflow of the sewage effluent; these samples gave the following results:—

Date.	Depth of feet from surface of coke bed.	Number of hours since effluent was removed.	Percentage of Oxygen in the air.	Percentage of Carbon Dioxide in the air.
Oct. 30, 1899.	13	2	19.1	0.8
do.	13	48	14.2	3.5
do.	13	104	18.6	0.2
Nov. 13, 1899.	13	4	19.0	0.8
do.	13	5	19.0	1.0

further treatment of the sludge by acid in order to set free the saponified fat. On the other hand, if the sewage were to be precipitated by sulphuric acid, it would be necessary to put down, in addition to the plant adopted at Roubaix and Tourcoing, such a system of tanks and filters, &c., as are usually required to treat the sewage of a manufacturing town uncomplicated by the difficulty due to the special character of the Bradford sewage. To treat the sewage of Roubaix it is estimated that twenty machines will be required. The cost of a machine is about £1,000, and the royalty on each machine is £600. In addition to this, M. Delattre is to receive 40 per cent. of the profits, which are estimated at £16,000 a year.

Surveying and Sanitary Notes.

Clones Sewerage.—The urban sanitary authority at Clones has decided upon carrying out a sewerage system for their town at a cost of £3,300.

New Italian Hospital Buildings in Queen Square, Bloomsbury, W.C., were opened by the Italian Ambassador on Wednesday last. The architect was Mr. W. Cutler.

Sheffield Sewage.—The Barnsley Sewerage Committee paid a visit on Thursday last to the Sheffield City Council's experimental plant at Wincobank for the bacterial treatment of sewage. The Council propose to purchase sixty acres of land, at a cost of about £250,000, for this purpose.

Plymouth Main Drainage.—The Plymouth Borough Council has decided to accept the tender of £20,997 of Messrs. Pethick Brothers for the construction of the main sea outfall in connection with the main drainage scheme, subject to an examination by their engineer of the figures on which the tender is based.

Institute of Sanitary Engineers.—At a meeting of the Election Committee held on March 14th the following gentlemen were elected:—As Members: A. R. Hutson (Gravesend), J. P. Jenkins (Penryn) and L. W. Wentel (Cape Town, S.A.). As Associates: J. E. Entwistle (Farnworth), H. Greening (London), J. H. Harris (Melton Mowbray), H. Maydue (Macclesfield) and W. A. Millward (Llandrindod Wells).

Bradford Sewage: The Frizinghall Experiments.—The members of the Bradford Sewage Committee visited the sewage disposal works at Frizinghall on March 6th. They inspected the works which are being carried out for the construction of a mixing-tank for the sewage. It is found that sewage entering the works from different parts of the town and at different times of the day differs materially in quality, being at some times heavily charged with dye waters and trade effluents, and at other times comparatively dilute. This variation occasions great difficulty in regulating the addition of the precipitation chemical, and makes it almost inevitable that an excess of the chemical should be added to ensure that the work should be done effectively. With the view of securing a sewage of a certain average quality and in a quantity sufficiently great to allow an experimental test to be made to ascertain the exact quantity of chemical to be added, a tank capable of containing a million gallons is being constructed at a cost of £700, into which the sewage shall flow immediately on reaching the works, and in which it shall be effectively mixed. The idea of the tank has been suggested by the city analyst, who estimates that the saving of precipitant effected by its use will be ten grains of sulphate of copper per thousand gallons treated, which would mean a saving of several thousand pounds sterling per annum to the city. These tanks are expected to be completed within a month or so.

"BUILDERS' JOURNAL" SHILLING FUND.

IT will be seen that our shilling fund on behalf of the Homes for Discharged Soldiers to be erected at Bisley now exceeds 2,000 shillings, but we feel sure that there are many who have not yet subscribed who will still further swell this total, and we hope that those of our friends who have taken collecting sheets will send them in at the earliest opportunity.

Our offer of a copy of the current issue of "Specification," the invaluable reference book for all connected with the building trades, sold at 5s. nett, is still open to anyone who collects twenty shillings for our fund.

The following subscriptions have been received since the publication of our last list:—

	Shillings.

The following additional contributions in money and kind have been received at the offices of the executive of the gift:—

FOR THE ENTIRE SET OF BUILDINGS.
Messrs. S. sons, Brothers and Co. (Hull).—Distemper.
FOR INDIVIDUAL SECTIONS OF THE WORK.
Messrs. J. Stiff and Sons.—Terra-cotta copings, sills, and air bricks for one Home.
Mr. Thomas Beck (Derbyshire).—The stone sills for one Home.
Mr. Walter T. Chapman (Cleethorpes, Grimsby).—The terra-cotta sills for a service block.
Mr. Ch. Burnley (Sittingbourne).—Fifty tons cement.
Messrs. Fredk. Walton and Co.—Dadoes of Lin rusta-Walton throughout the halls, staircases and landings of the Homes.
The Wall Paper Manufacturing Co.—Dadoes of Analagya throughout the living rooms, corridors, and lavatories of the Homes.
Messrs. Starkie Gardner and Co.—Art metal work to the value of £50.
The St. Pancras Iron Co.—Two iron stair cases.
Messrs. Richmond and Co., per Mr. W. Sapcott.—Six gas cooking stoves.
Messrs. T. and R. Pote.—100 yards flooring tiles.
Messrs. Farmer & Bindley.—20 yds. sup. marble paving.
The National Opalite Glaze Brick and Tile Syndicate, Ltd., per Mr. W. Griffiths.—500ft. super white opalite tiling.
The Meadow Foundry Co. (Mansfield).—Four manhole covers and frames.
Mr. Samuel Wright (Hackney).—Fibrous gornices to the value of £10.
Messrs. George Caston and Co.—Wrought-iron grilles and fancy work.
Messrs. Nash and Hull.—Wrought-iron ornamental grills with metal letters.
Messrs. George M. Callender and Co.—Bitumen sheeting for the whole of the verandahs, covered ways, and also for tanks.
The Burmantofts Works (Leeds).—Four fire-places in Faience.
Messrs. John Shelbourne and Co.—The architraves for one Home.
Messrs. J. Young and Co.—Eye inspection covers for the whole of the drainage system.
Messrs. Lawford and Co.—Asphalte paths.
Messrs. H. and F. Boenten.—Wrought-iron mouldings for entrance gates.
Messrs. A. J. Arrowsmith and Co.—One pine chimney piece.
The Accrington Brick and Tile Co. (Accrington).—2,000 red facing bricks.
Messrs. Candy and Co. (South Devon).—5,000 brown glazed bricks.
Mr. H. A. Ball.—A 4ft. 6in. double oven kitchen range.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"Were it not wonderful, had Orpheus or Amphion built the walls of Thebes by the mere sound of his lyre? Yet tell me, who built these walls of Weissnichtwo; summoning out all the sandstone rocks, to dance along from the Steinbruch; and shape themselves into Doric and Ionic pillars, squared ashlar houses and noble streets?"

* * * * *

"Is that a wonder which happens in two hours; and does it cease to be wonderful if happening in two million? Not only was Thebes built by the music of an Orpheus, but without the music of some inspired Orpheus was no city ever built, no work that man glories in ever done."—CARLYLE.

The Theatre Francais. M. LEYGUES, Minister of Public Instruction and Fine Arts, introduced a Bill in the Paris Chamber last week proposing that a credit of two and a half million francs should be opened for the reconstruction of the Théâtre Français. The Bill was referred without comment to the Budget Committee, though there is little doubt that the credit will be granted. Certain deputies who are noted for their opinions on art are likely to cause delay, as they propose to discuss the advisability of rebuilding the theatre as it existed, with the simple addition of a few extra exits. M. M. Stanislas Ferrand, the Seine deputy, and an architect by profession, announces his intention of asking that there shall be a competition among architects for the design, and he is also of opinion that the theatre should be completely isolated, which could easily be done by making short streets on the Rue Montpensier and Council of State sides of the Théâtre Français. In this way the theatre and the Palais Royal would be both completely isolated; but it is feared that the proposal would entail too much delay, and that there are many other difficulties which must prevent its adoption. The work of shoring up parts of the ruins of the old theatre is being proceeded with. The great cupola is still intact, but the architect, M. Guadet, fears that it will have to be destroyed, as also the facade on the Rue Montpensier.

A new American Palace. A NEW mansion has been built at the corner of Fifth Avenue and Sixty-eight Street, New York, for Mr. William C. Whitney. About £200,000 has been spent on the decoration of the two lower floors. Mr. Whitney said he would never have selected the Italian Renaissance as the period of the decorations if he had known the difficulties of the work. All the decorations had to be brought from Italian palaces, and that is difficult to-day. The entrance of the house, which is now on Sixty-eighth Street, leads down a flight of marble steps to a broad, low hall. Through a carved marble archway is the hall to the servants' quarters. On Fifth Avenue are Mr. Whitney's office and a reception room done in Rococo fashion, with grillings of gold on mirrors, in the centre of which are paintings, ornately framed in gold. A broad marble stairway leads to the main hall, which occupies a quarter of the main floor. The white marble walls are hung with a set of Italian tapestries that are said to be the most valuable in America. The ceiling came from the Barberini Palace in Florence. It is divided into sunken squares of blue and gold. The mantel which stands in this room is of elaborately carved white marble, and is famous in the history of European architecture. It is Italian, but came directly from Paris. A winding stairway in white marble leads up to the living rooms. On the Fifth Avenue side of the house on the main floor are a drawing-room and library. The former is hung in gold and maroon silk and velvet tapestry brought from a Florentine palace. The drapery covers the walls except for the

spaces occupied by the few paintings. Adjoining this room is the library. Superb carved black oak bookcases are about the walls, and the mantel is of delicately carved white marble. The walls of the dining-room, which also boasts a ceiling from the Barberini Palace, are entirely covered with paintings brought from a palace outside of Genoa. The conservatory is decorated with marbles brought from an Italian garden, and leads from the dining-room into the ballroom, which is the most beautiful apartment in the house. The walls as they stand came from the chateau of Phœbus d'Albert, near Bordeaux. It was built by this nobleman, who was one of the favourites of Louis XIV. In the time of Louis Philippe the walls, which are of polished oak, exquisitely decorated in a design of gold, were brought to Paris. The decorated ceiling alone is new. The dark brown oak, with the gold decorations, contrasts exquisitely with the draperies of light maroon. It is approached not only through the dining-room and conservatory, but by a long hall done in varicoloured woods, imported from an Italian palace.

Forum Excavations. A LARGE well, with its mouth sharply cut in the Etruscan manner, has been discovered in connection with the Forum excavations. Five of the broken columns of the Basilica Æmilia are being pieced together; and the opinion gains ground among serious students that when Pliny wrote "Phrygian" he intended the marble nowadays called "Africano." Not a single chip of Phrygian marble has been found during the excavations on this site; while the other precious marble has literally abounded; and lo, here are several columns of it belonging to the inner naves of the building! This is rather a blow for those who theorised that the columns of the former Basilica of S. Paolo outside the walls had been taken from the Basilica Æmilia in the Forum, by Theodosius and Valentinian. The fact is that the columns destroyed in that church in 1823 were of dimensions far larger than even those of the outer porticoes of this pagan Basilica, so that theory may be dismissed.

Smoke Abatement. THE Coal Smoke Abatement Society has completed the first year of its existence. Sir William Richmond (as president) says, in the first report (for 1899), that the Society's sphere of action is (1) the enforcement of existing legislation against smoke nuisances through the Public Health Act (London), 1891, and the amendment of that law where necessary; and (2) investigation into the causes of, and remedies for, this evil in general. Their chief work during the past year has been to put into action the machinery already provided by the law for the prosecution of offenders by the competent local authorities. The first step towards this was the appointment of Mr. Petty as inspector, who has reported no less than 1,250 observations. He has been instructed in 680 cases to present to the vestries official complaints, which have led to their giving statutory notice in a large number of cases, and taking proceedings in sixty-two, with the result that in thirty the nuisances have been entirely suppressed, and in thirty-two others very much lessened. The small proportion that convictions bear to complaints is owing partly to the inevitable opposition from interested parties, and partly to defects in the Acts of Parliament which magistrates have to apply. This opposition, there is reason to hope, is gradually being overcome, and to remedy the state of the law a short, but sufficient, Smoke Amendment Bill has been drafted, and will be introduced into the London County Council by a member of the Committee of the Smoke Abatement Society. Besides these direct consequences of activity, it is difficult to estimate the good which has undoubtedly been done by educating public opinion and stimulating interest in this matter. This has been evinced by the increased energy and independent action on the part of the local authorities, and still more by the salutary deterrent effect traceable in the number of chimneys and furnaces which now

take steps to conform to the law, but a large portion of which would otherwise be still offenders.

The Work to be done. THE disappointing fact, says Sir William Richmond, that no more than 400 persons have become members of the Society (though the subscription is only 5s. a year) can only be explained by the difficulty there is in getting the public to understand that this first part of the programme is really attainable, if only the limited circle of subscribers can be enlarged. There still remains untouched the other larger, and harder, part of the task, which is no less than to discover some means of obviating the evil from the smoke of the vast number of chimneys of the private dwellings of London; and this has not been neglected by the society. At the Building Trades Exhibition in May last the Society organised a separate section of smoke preventing appliances, and offered prizes for the most efficient. The competition was considerable, and medals were awarded to the best inventions, but none were found altogether satisfactory. A technical committee has been formed to examine and report on the means of preventing smoke from private dwellings—without any extra expense for fuel—a condition of success which, for the present at any rate, seems to be indispensable.

A Discovery of Frescoes. AT Bosco Reale, near Naples, where for some time past excavations have been slowly going on in the grounds of a villa called Voua, belonging to the De Prisco family, an important and interesting discovery of frescoes has just been made. A huge peristyle and four large chambers have been discovered, on the walls of which are about twenty frescoes of large dimensions, rich colouring, and of a design hitherto unequalled in any brought to light in the Pompeii district. Most of the figures are full sized and more carefully executed than any hitherto known. Rich mural decorations, fresh in colour and perfect in drawing, cover the parts of the walls not occupied by the main frescoes. Unfortunately for students of art, it is feared that exposure to the air and the light will cause these magnificent paintings to fade as quickly as those at Pompeii and in the Naples Museum. Every effort is being made to preserve them as long as possible, but lovers of art are taking advantage of the opportunity to see this unrivalled example of pre-Christian mural decoration before it fades.

London's New Boroughs. THE Commissioners appointed to determine the metropolitan boroughs under the London Government Act, 1899, have now practically finished their task. Areas which once had 200 or 300 vestrymen on three or four separate vestries, with district boards intervening, are now linked up into one borough, and given some forty or fifty representatives only. Now the hundred odd districts of London have been swept into twenty-eight large and compact boroughs. This simplifies matters a good deal. For instance, the East-end, instead of having three district boards and about a dozen vestries, will consist of two boroughs only. From the City to Burdett Road will be the new borough of Stepney, and from Burdett Road to the Lea will be the new borough of Poplar. Most of the Central district, where formerly were the vestries of Clerkenwell and St. Luke, together with portions of the Holborn District Board, including the Liberty of Glasshouse Yard, will be the Borough of Finsbury. The multiplicity of parishes and "liberties" around St. Giles become with Gray's Inn and Lincoln's Inn the borough of Holborn. South of the river, Bermondsey will take in all the parishes of the St. Olave's district, part of St. George the Martyr, and the whole of Rotherhithe. The outer areas for the most part remain the same. Nearly all the outer boroughs have enormous areas. Wandsworth has an area of 9,285 acres, Islington an area one-third smaller; yet Islington has the largest population of any of the boroughs, and Holborn, with 67,490 inhabitants, has the smallest.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Tenancy Agreements.

HARPENDEN, HERTS.—A. H. S. writes: "Can I legally prepare an agreement of tenancy for a period of six years—(a) for a client, making a charge for it; (b) making no charge; (c) for some of my own property?"

(a) Yes, if it be under hand only; if under seal, it is illegal to prepare it, the penalty being £50 (Stamp Act, 1891, section 44). (b) Yes, whether under hand or seal. (c) Same answer, if gratuitous or not under seal. H. P. B.

Books on School Buildings.

SOUTHEND-ON-SEA.—A. H. S. writes: "Which is the best book published on the planning of public elementary schools? Also, the price and publishers."

These are good books:—"Technical School and College Buildings," by E. C. Robins, F.S.A. Price, 18s. net. "School Architecture," by Palliser, Palliser and Co., architects, New York. Price, 4s. 6d. net. "Modern School Buildings," by W. R. Briggs, F.A.I.A. Price, 17s. net. These are obtainable from Mr. B. T. Batsford, 94, High Holborn, W.C.

French Technical Publications.

SOUTH TOTTENHAM, N.—E. C. D. writes: "(1) Do you know of a French journal dealing with the building and allied trades? I should like to know if there is one giving special attention to sanitation. (2) Can you recommend an English-French technical dictionary?"

(1) "La Construction Moderne" (weekly) will doubtless suit your requirements. It can be obtained for £1 15s. per annum, post free, or for £1 10s. if called for at Messrs. Grevel and Co., 33, King Street, Covent Garden, W.C. Subscriptions start only from April 1st and October 1st. (2) We are not aware of a dictionary exactly similar to the one you desire, but there is the "Technologische Wörterbuch" (Part 2, English-German-French), published by Tolhausen, of Leipzig, at 10s. 6d. This can also be obtained from Messrs. Grevel and Co.

Acknowledgments and Lapses.

HORTON, BRADFORD.—F. L. S. T. writes: "Owner A agrees by deed to pay B 5s. every half year as acknowledgment for B allowing A to take his w.c. waste to B's cesspool. Owner B agrees by deed to pay A 5s. every half year as acknowledgment for A allowing B a right of way over A's property. The deeds are dated March 20th, 1882. Neither party possesses any receipts for acknowledgments paid, and A says none were paid. Please say when the rights will lapse if no payments are made."

Having regard to the fact that the two deeds were executed contemporaneously, and that the half-yearly payments were identical in amount, we think that the parties must be taken to have agreed that these payments should be taken to have been made, without going through the form of each handing over to the other the amount due from him. We do not think that the rights will lapse by reason of the want of actual payments in cash.

H. P. B.

Roof for Billiard Room.

LORKS.—AN ARCHITECT writes: "I should be glad if you would inform me whether there is any danger of leakage, either from condensation or other causes, on to the billiard table from the skylight, illustrated on page 25 of your issue of February 14th, or is it necessary to put in a counter light to obviate this?"

Also, is there any objection to a lead flat and lantern combination? Would you recommend the following form of roof (sketch not reproduced)? The skylights in this case would, I presume, require to open for ventilation, or would there be sufficient air from the side windows?"

There should be no danger from leakage or condensation if the skylight is properly made. There should be an internal gutter all round in the cornice. There would be no objection to a lead flat and lantern, but it would have to be carried by rolled steel joists of large size. The alternative suggested, of a collar-beam roof with skylight in the sloping sides, would be very unsightly. HENRY ADAMS.

Value of Country Architect's Practice.

WINDERMERE—NORTH COUNTRY writes: "Can G. A. T. M., or another of your experts, give me an idea of the value of a country architect's practice in a growing neighbourhood which is bringing in about £750 a year?"

An architect's practice is so largely personal that its value is extremely difficult to determine. As a general rule two years' purchase is the utmost that can be obtained, but it may be worth as much as three years' purchase if it depends upon several appointments which are likely to be of a permanent nature even after the incoming of a new partner, and to yield a definite income. On the other hand, if the practice depends upon one man's artistic reputation, a share in it may not be worth very much, and any sum put into the business ought to be covered by a life policy. To purchase a practice right out without several years' introduction as a partner would be most unwise. G. A. T. M.

Wires in Levels.

RYDE, I.W.—X. Y. Z. writes: "I have just received a 'Troughton' level on tripod (18in. telescope, 11in. spirit-tube, 4in. compass) and find that there are + wires at the eye-piece end only of the telescope, and at the object end no wires at all. Will you kindly say if this is right? I see no provision for wires at the object end, unless a brass ring directly behind the lens is missing."

The cross wires of level are placed in the diaphragm or brass frame near the eye-piece, at the point of intersection of the foci of the eye-piece and object glass. Although called wires, they are made of spider web strained across the opening. In the smaller levels there is one horizontal wire and one vertical wire crossing the optical axis; in the large levels there is a similar horizontal wire, but instead of a single central vertical wire there are two vertical wires, spaced so as to show the level staff between them. When the level is to be used for reading distances, two other horizontal wires are inserted, spaced to read, say, 1ft. on staff at a distance of 100ft. No telescopes have wires at the object glass.

HENRY ADAMS.

Income Tax Returns.

LITTLEHAMPTON.—INCOME TAX writes: "I should be glad to know, being connected with a small builder's business, how to prepare a statement to show what is required in a return under schedule D. I keep a profit and loss account, and I prepare a balance sheet of assets and liabilities. Can I determine from these what is required?"

Persons assessed under schedule D income tax must subscribe their names to a statement of the profits of their trade, forms of which are to be obtained from the surveyor of taxes for the district. It is not quite clear what you require, but if you only require a form of account on which to base the statement you will make as to the profits arising from a builder's business only, then your own accounts, showing the net profits arising from the business, will do for this, taking care not to make any deduction for household or living expenses, as you are assessed on the profits arising from your business, which latter has nothing to do with your living. These profits you subscribe your name to on one of the forms supplied by the surveyor of taxes as stated.

If, on the other hand, you have not hitherto been assessed under schedule D, but under schedule B, as a farmer, you must be prepared to sign a statement of the whole of the profits arising from any and every trade you are connected with, on a special form to be obtained from the surveyor, and if you can prove that your profits have fallen short of the sum previously assessed under schedule B within three months of the year of assessment, the excess paid under schedule B will be certified to be repaid to you. C. BRAND.

Liability of Tenant to Repair Drains and Closets.

HASTINGS.—W. T. R. writes: "A tenant occupies an old house on a repairing lease, and the drains and closets are scarcely sanitary. Should they be condemned by the borough authorities, would the tenant be compelled to reinstate a modern system under his covenant to repair, or would it be the duty of the owner to do so? If not actually condemned, could the owner in any way be compelled to replace existing closets with effective appliances?"

The occupier is not obliged under his covenant to repair to put in a modern system of sanitary arrangements. Under section 23 of the Public Health Act, 1875, if a house is without a drain sufficient for effectual drainage, the local authority may, by notice, require the owner or occupier within a specified time to make a proper drain, and, if this notice is not complied with, may do the work and recover the expense from the owner. Similar provisions are by section 36 made with respect to insufficient water-closets. Unless such a notice was served, I do not think that the owner could be compelled to replace the existing closets with effective appliances. H. P. B.

Requirements from an Architect.

BATH.—R. M. E. C. writes: "I am desirous of becoming an architect. What are the subjects I should be acquainted with? Are geology and advanced mathematics necessary? What age should I be?"

A knowledge of geology may be of the greatest possible value to an architect, but it is by no means essential. The same may be said of almost any other branch of education. A man who is master of trigonometry and the calculi is sure to find them of great use to him, yet he will probably never miss them, never know that he has lost anything, if he knows no more of mathematics than is contained in the first two books of Euclid and the elements of algebra. In short, the better educated a man has been the better architect he is likely to become, other things being equal; but, above all things, draughtsmanship is necessary, and should be cultivated from early school days. In most cases, it is best to sign articles between the ages of seventeen and nineteen, for three years, and then to pass as an assistant from office to office, to acquire varied experience, during the next few years. G. A. T. M.

Charges for Preparing Valuations.

LONDON, W.C.—E. B. writes: "What are the charges for preparing a valuation for purchase by a company of a freehold factory (about £30,000)? Also the charges for preparing schedules and valuation of the trade fixtures, furniture, plant, horses and carts, &c."

The amount of the valuation and the percentage charged for preparing it will be different if the company has powers to purchase under compulsion to the amount and charge made otherwise than under compulsion; but, unless it possess compulsory powers, a company is charged as a private individual. You do not state that the purchasers have powers of compulsory purchase. The following is the scale of charges of the Royal Institute of British Architects for the valuation of freehold, copyhold or leasehold properties:—On the first £1,000 the charge is 1 per cent.; thence to £10,000, $\frac{1}{2}$ per cent.; and on the residue above £10,000, $\frac{1}{4}$ per cent. For preparing a valuation of fixtures, &c., the professional charges are:—5 per cent. on the

amount up to £500, and 2½ per cent. on the remainder, in addition to stamp and expenses. The preparation of schedules is the usual accompaniment of the preparation of a valuation list, and is included in the charge. Horses are different, the charge made for valuing them being similar to the usual charges for other farm live-stock. You must bear in mind that, although it is unwise and indeed unfair to other valuers to depart from the recognised scales in ordinary cases, a reduction is often arranged between the parties in dealing with very large amounts which entail less labour in proportion to the amount of the claim. With regard to this you must use your own careful discretion.

E. BRAND, P.A.S.I.

Piling Foundations.

GREENOCK.—J. R. writes (and the answer given is also in reply to "Alpha," Northampton): "What method of pile foundations is required for a building 170ft. by 130ft., the walls of ground floor and basement being 2ft. 6in. thick. The soil is an estuarine deposit about 50ft. in depth. Will thin internal walls and piers also require piling? How would I arrive at the cost of such foundations? In cubing the building must I take half-way down the piling?"

The best method to employ can only be determined by an inspection of the site and a full knowledge of all the requirements of load, &c.; but, approximately, if the deposit has solidified and is thoroughly dry, the method described and illustrated on page xlii of the supplement to the BUILDERS' JOURNAL for September 13th, 1899, would be suitable. If, however, the deposit is unstable, it would be imperative to sheet pile the whole site so as to retain the soil, depositing a sufficient depth of concrete on the wall foundations. A cross row of piles under the principal interior wall might be used with advantage to tie together the boundary piling. More exact information would decide whether it would not be more economical to sink brick or concrete piers down to the firm subsoil and throw girders across their heads for the foundations.

G. E.

In preparing an estimate for a building on pile foundations, the building would be cubed in the ordinary way and the cost of piling added separately.

HENRY ADAMS.

Openings in South Africa.

PAIGTON.—PRACTICAL writes: "I have served nearly five years with an A.R.I.B.A.; have a certificate in "The Principles of Sanitary Plumbing" from the London and City Guilds Institute (Ordinary Grade); have also attended the local technical class for two winters in carpentry and joinery, and am accustomed to prepare plans from rough sketches and to survey sites, &c. I consider I have a fair practical knowledge of building construction. Do you think I might get a better chance in South Africa after the war? What branch of the building trade would you advise me to apply for work in? An open-air life is preferred—as much as possible. I shall have excellent testimonials. My idea is to become a builder, being a small capitalist."

We think it would be better for our enquirer to wait until the war is over before making up his mind. There will no doubt be a large amount of building done when things have somewhat settled down, as the country is by no means largely developed. We consider the idea of starting as a builder and contractor with a small amount of capital, considering the knowledge our correspondent has acquired, a good one; but he will, no doubt, be able to form his own opinions as to the opportunities of the country from the able paper by Mr. John Begg, which appeared in our issue for March 7th.

R.I.B.A. Testimonies of Study.

CULLEN, N.B.—S. W. C. writes: "In studying for the R.I.B.A. Intermediate Examination, what subjects would you suggest for testimonies 3 and 6 (Classic and Gothic Ornament)? Are you supposed to make one

complete study or several in these sheets? Will you publish any more 'Model Answers'?"

It is best that both these sheets should be measured. A very favourite subject for the Classic Ornament is the well-known frieze from the Erechtheion, now in the British Museum, and a cast of which can be obtained from Brucciani, plaster modeller, Drury Lane, W.C. Many students, however, make up this sheet of fragments copied from such books as Spiers' "Orders." A carved capital or a bench end from some local Gothic church would form a good subject for the sheet of mediæval ornament. Such a thing is to be found in almost every English village, but more rarely in Scotland, Ireland and Wales. Brucciani might again be consulted, and a cast obtained, say, of one of the spandrels in Stone Church, Kent.

G. A. T. M.

[The "Model Answers" we have already given would we think be useful to architectural students generally as well as to candidates for the particular examinations dealt with, and to give model answers for all the examinations that appeal to students in architecture and the various building trades would make too great a demand on our space.—ED. B. J.]

Architect's Fees for Work not Carried Out.

KIRKCALDY.—LADYSMITH writes: "A proprietor asked an architect what the total cost would be for the erection of a certain building. The architect told him that £570 would be the probable cost and this satisfied the proprietor, as he was not prepared to spend more. The architect was instructed accordingly to prepare drawings, &c., and obtain tenders, which latter (to the extreme disappointment of the proprietor) exceeded £1,200, and caused the matter to drop. The architect sends in an account of fifteen guineas for his services, and I should be glad to know whether he can justly claim it, and, if so, on what grounds; or, if not that sum, how much can he claim?"

The architect is entitled to be paid his fair charges for the work actually done. If the client expressly and distinctly instructed the architect to prepare plans, &c., of a building that would cost not more than a certain sum, or would cost about a certain sum, and the architect prepared plans of a building that could not be erected except at a much greater cost, the client would be entitled to repudiate the plans and refuse to pay anything for them. (See *Burr v. Ridout*, reported in the "Times" newspaper of February 23rd, 1893.) But that is not our correspondent's case. The proprietor appears to have been satisfied with a rough estimate given by an architect in conversation, and to have given instructions to prepare the plans, without in any way giving the architect to understand that the building was not to cost more than the amount of that rough estimate. What the fair charges for the work done would be, it would be impossible to say without knowing what the work was. It has, however, been decided that an architect is not entitled, when the matter falls through, to be paid the percentage which he would have received if the building had actually been put up. *Farthing v. Tomkins* (1893), 9 Times L. R. 566.

H. P. B.

London Water Supply.—On Wednesday last a deputation from the London County Council was received by Mr. Chaplin, President of the Local Government Board, at the House of Commons, on the subject of the Bills now before Parliament relating to the water supply of the metropolis. Mr. Chaplin pointed out that the proposal to get water from Wales was in direct opposition to the recommendations of the Llandaff Commission, which reported that the scheme for storing water at Staines would be much cheaper. However, after hearing Mr. Dickinson, he would like to consider the matter more carefully before making any definite statement, but he did not wish to hold out any hopes to the deputation, as he had received representations only a day before from the metropolitan M.P.'s asking him to take an exactly opposite view.

Professional Practice.

Bristol.—The recently opened mission church of St. Aldhelm, Chessell's Road, Bedminster, is in the Gothic style, red Winterbourne stone being used, with Bathstone dressings. It has an open timber roof, left in its natural state, covered with Major's patent interlocking plain tiles. At the east end, and raised three steps above the floor of the nave, is a spacious chancel, to be fitted with choir stalls, room being left for a full-sized two-manual organ. The sanctuary is raised one step above the floor of the chancel, and divided from it by an oak rail resting upon wrought-iron standards of ornamental design. The church has an aisle on the south side, divided from the nave by arches and columns of Bath stone. The aisle is divided by sliding swivel partitions, forming five roomy classrooms for Sunday School purposes, each classroom being 16ft. square and having separate windows. These partitions are made to fold back into a very small space for matins and evensong services. At the west end are two spacious vestries for the clergy and choir, and the latter vestry will also be used as a teachers' room during Sunday School hours. Beneath the vestries are a kitchen, a heating chamber, and various offices. The clergy and choir vestries have separate entrances. On the north side is the main entrance porch, the floor of which is laid with encaustic tiles, and also the entrance lobbies to the vestries. In the east and west gables there are tall, three-light lancet windows, and the whole of the windows are glazed with cathedral glass in lead squares. Much attention has been given to ventilation, and the heating is by hot water on the low-pressure system. The church has been planned to seat 700 worshippers. The architects were Messrs. P. Munro and Son, of Bristol, the contractor was Mr. E. Walters, of Montpellier, and the heating apparatus was supplied by Messrs. Willway and Sons, of Bristol.

Perth.—An electrical generating station is to be built on ground adjoining the river Tay, to the north of the smallpox hospital, with a frontage to the Harbour Road of 120ft. The buildings include an engine house (115ft. by 42ft.), a boiler house (115ft. by 38ft.), a battery room (48ft. by 31ft.), workshop, store, and lavatory accommodation for engineers and men. The test room and offices are at the front, and over these a dwelling-house is provided for an engineer, who will look after the works. The chimney is circular and 150ft. high, and so situated and constructed that it can be utilised as the chimney of a refuse destructor. The buildings throughout are to be built of red facing bricks, with moulded courses in front, round arches for windows, and large entrance doors to engine and boiler houses. The plans have been prepared by Mr. M'Killop, borough surveyor, with the direction of Mr. Hawtayne, electrical engineer. The cost will be £7,428.

Harrogate.—For some time past the Spa Concert Room, particularly since it became the property of the Corporation, has been much too small for the requirements of the Harrogate season, and it is proposed to build a new Kursaal on the Spa Estate, and adjoining the existing building. At the meeting of the Harrogate Town Council on March 12th it was resolved that the architect (Mr. Robert J. Beale, of Westminster) should prepare specifications, quantities, and an estimate for the Kursaal, in order that the Town Clerk might make application to the Local Government Board for the loan. For the new building it is proposed to clear away the glass and iron structures at the left of the Colonnade, and place the new building on the site of the old skating rink and on the west side of the existing promenade, forming a connection with it and so allowing the whole to be used in common or subdivided when necessary. The main entrances to the new building are provided under a covered portico leading into a grand vestibule, from each side of which are spacious promenades going all

round the main concert hall, with two staircases leading to the balcony, smoking and billiard room on the first floor. The new concert hall will provide seating accommodation for about 2,500 persons, and will be roofed in one span. A large portion of the ground floor will have a special polished parquet floor, which can be cleared for dancing; the seating at the back of the hall will be raised so as to give a clear view of the stage and form a pleasant lounge during dancing. On each side of the hall are provided small boxes, with glazed partitions at back, formed to slide up when required, thus providing small balconies from the promenades. The stage provides for a full band and orchestral chorus, and by means of ornamental wings hung at the sides of the proscenium the width of the stage can be reduced when required for dramatic performances. Ample exits are provided for any emergency. At the back of the main hall facing the grounds is a café and refreshment room, and on the lower floor, level with the garden, a reading room. From the promenade a flight of steps will lead to the gardens, also a way for bath-chairs. In the lower ground floor are provided rooms for the chorus and band, lavatories and cloak rooms. The whole of the building is intended to be finished and decorated throughout in a style suitable for the requirements of a thoroughly up-to-date Kursaal. The services of Mr. Frank Matcham, who acted as assessor, have been specially retained by the Corporation. It is estimated that the new building will cost £25,000 or £30,000.

New Patents.

These patents are open to opposition until April 21st.

1899.—Theodolites.—3,064. G. A. HALL, London, S.W. A rectangular telescope with cross webs and stadia lines is attached to a clamp rest, which forms the upper hemisphere of a metal ball. This hemisphere is hollow and leaves only the bridging pieces for support, so that a compass with an "all way" spirit level in the lower half of the ball can be read. There is a vertical and horizontal circumferential, with verniers and microscopes attached to the telescope and socket, and the lower ball can be clamped in any position. The telescope is set to a true level by means of a spring clip and a slow motion screw. It is mounted on a swivel neck, which allows it to be revolved horizontally without losing its level.

Plaster Slab-making Machinery.—3,789. G. B. HALL, London, N. This apparatus is for producing plain or ornamental slabs of plaster, cement, or other composition, and is an improvement on patent No. 1,256 of 1895. The materials are mechanically mixed, delivered to a rolling machine, and rolled into sheets. The feature of the present patent is that the proportions of the ingredients can be varied to produce a slab having one side "keyed."

Breakwaters, Submarine Piers, &c.—5,456. N. R. JECKEL, Jutland, Denmark. Profile girders are erected vertically or obliquely and the building blocks are slid down them, an interlocking arrangement being provided.

Manholes.—5,999. J. KNIGHT, London, S.W. This is an improvement on patent No. 17,733 of 1893, and consists in adding a surface of glass, enamel, or other equally impervious material to form the lining of the manhole. This surface is preferably formed conjointly with the manufacture of the artificial stone.

Trough Closets.—8,280. W. OATES, Halifax. The object of this invention is to dispense with the loose bend for supplying the flushing water. At the flushing end is formed integral a bend having a socket at the top to receive the lower end of the supply fall pipe.

Cutting up Long Shavings.—13,626. T. N. ROBINSON, Rochdale. Long shavings, like those from floor-board planing machines,

are cut up by being caught by and passed through rollers and fed to a rotating cutter below.

1900.—Water Filters.—147. W. L. TETES AND J. A. HEANY; both of Philadelphia, U.S.A. Before the water is passed to the filtering material it is electrolysed in order to decompose and sterilize it.

The following specifications were published on Saturday last, and are open to opposition until April 28th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—3,620, A. WARBURTON, A. BAILEY, and HARRY ROTHWELL, continuous draught kilns for brick and terra-cotta burning. 3,701, BERRY, slugging or nailing machines. 3,786, LORRAIN (*Macdonald*), electric incandescent lamps. 3,814, HEARNE and WHITEHEAD, ventilator. 3,934, LICENSE, clamps and vices. 4,199, BLACKETT, means for operating fanlights and ventilators. 4,344, MARCHAND, manufacture of articles of glass by moulding, casting, or blowing. 4,589, HENTZE and MULLER, method of producing hard mantles or hoods for incandescent light. 5,356, BENNETT, electric arc lamps. 5,587, Titus, road scrapers. 5,627, MARTIN, adjustable shelf bracket. 6,113, HECKFORD, means of fixing cap or back plates of lock and latch cases. 6,485, COLE, hydraulic cranes and lifts. 6,608, HOLLOWAY AND DELLAGANA AND CO., LIMITED, liquid spraying apparatus adapted for colour slip glaze and enamel spraying. 6,609, HOLLOWAY AND B. DELLAGANA AND CO., LIMITED, means for effecting the coloured decoration of pottery. 6,718, DAWSON, folding ladder. 7,556, PERCY, automatic acetylene gas generator. 7,740, DALY, pickaxe, adze, or hoe. 7,801, HUGHES, machinery for pressing bricks. 8,168, MOUL AND LIND, mounting incandescent electric lamp bulbs. 8,234, DALBY, locking apparatus or devices for bolts, nuts, manhole doors, &c. 8,272, PARNALL, BARTER, AND PANES, dovetailing or woodworking machine. MORRISON, water-closets. 8,368, KEITH, sectional hot-water boilers. 8,416, SWARBRICK, draught excluder for doors. 8,497, BARTENSTEIN, bulbs for electric incandescent lamps. 8,648, THOMPSON (*Wegmann-Hausser*), acetylene gas generators. 8,730, PEARSON, hay racks and feeding troughs for cattle sheds. 9,042, BRANDT, pipe joints. 10,456, HEINTZ, file-cutting machines. 18,112, GILMOUE, method of manufacturing lumber. 18,401, THUESTAD, door holders. 18,498, PEISTER, PAETZ, and LEWIN, dyeing of wood. 19,334, MARTINOLI, rotary engines, pumps, and meters. 20,712, LAKE (*Stackmann and Retschy's Chemical Works*), process for the production of disinfecting powder. 21,381, McDONALD, mitre boxes. 21,779, STRAUB, process of treating lime in the manufacture of plaster and cement. 24,110, SHIELD, cramps for cramping together blocks of concrete or stone in breakwater works. 24,753, FORIN, sash fasteners. 24,991, KEMP, brackets and chandeliers for gas lighting, etc. 25,098, LUSK, window fastening. 25,305, BERGER, planing machines.

1900.—343, O'SULLIVAN and BOARDMAN, nut locks. 563, IWASZKIEWICZ, padlock. 884, MARECHAL, locking bolts and nuts. 903, JACKSON, tramcar or omnibus seats, garden chairs, etc. 969, WILKEN, roofing tiles. 1,009, McCABE and GOUGHENOUR, electrically or magnetically operated locks. 1,054, CLARK, syphon flushing cisterns. 1,220, IMRAY (*McDowell*), wall ties. 1,360, ROWELL, metal fencing.

Bloemfontein is well laid out with a large market square in the centre. Many of the houses have luxuriant gardens, shaded by willow, gum, and other trees. The residence of the President is a stone-built house, and cost £15,000. The new Raad Zaal is an imposing building, with Doric columns and a tower 90ft. high. It was erected at a cost of £57,000. The old Raad Zaal is used for Government offices. Another prominent building is the Grey College, which was presented to the town by Sir George Grey.

Builders' Notes.

Workmen's Homes for Plymouth.—The Plymouth Borough Council has decided to accept Mr. H. E. Skinner's tender (amounting to £6,349) for the erection of blocks 13, 15, and 19 of the workmen's homes at Prince Rock, upon the understanding that the architects should from time to time during the progress of the work make such modifications as the Committee might approve in order to reduce the cost of the buildings.

Picketing and Assaults.—At the Guildhall last week two labourers, named Bignell and Burns, were charged with assault. Mr. Biron stated that he prosecuted on behalf of Mr. Shepherd, a builder, who, in consequence of the attacks made on his men, felt it necessary to take these proceedings. Mr. Shepherd had some building going on in Norwich Street, Fetter Lane, and from the very beginning of the work the place had been picketed. Finally, the prisoners assaulted two men, injuring one of them so seriously that he remained insensible for seventeen hours. John James Hunt, foreman to Mr. Shepherd, said that the picketing had been going on in connection with the Operative Bricklayers' Society. Burns was sentenced to two months' imprisonment and Bignell to a fine of 40s. or one month.

London County Council.—At last week's meeting of the Council Mr. W. H. Dickinson was elected the new chairman, and Mr. A. M. Torrance the vice-chairman. Among other suggestions, the Housing of the Working Classes Committee expressed the opinion: "That the law should declare that it is the duty of the freeholder to see that dwelling-houses on his property are fit for human habitation by enforcing the repairing clauses in his leases, and taking all other necessary steps. Where an official representation under the Act has declared that the dwelling-houses in question are not fit for human habitation, the freeholder should have the power to re-enter into possession, but there should be put upon him the obligation to rebuild upon the site dwelling-houses for the working classes. In the event of the freeholder not fulfilling his obligation, the local authority should be empowered to take possession of the land, paying only the market value of land subject to the obligation to rehouse persons of the working classes on that site." The Committee recommended that their action be approved. This was agreed to. It was decided that, subject to the assent of H. M. Commissioners of Works, a site to the west of St. Clement Danes Church should be allotted to the Gladstone Memorial Committee.

A Party Wall Action.—The case of *Watts v. Lapham*, the hearing of which occupied a considerable time at the Bristol County Court recently, was concerned with the rights of neighbours to use party walls. Plaintiff's claim was £50 for damages for trespass by defendant and interference with his ancient lights, and he alleged that defendant in building a shop out from his premises had wrongfully built upon a wall between the plaintiff's and defendant's property, which the plaintiff alleged either was wholly his own wall or a party wall. Mr. Pizey, a surveyor and architect, was called to prove the damages, which he estimated on the basis of a diminishment in the letting value of £10 per annum. In cross-examination, however, he admitted that the bulk of this was due not to the obstruction of light, but to the fact that a business was brought next door to the plaintiff. Dr. Grey, for the defence, argued that the wall was a party wall, and by common law the owner on either side of the party wall had no remedy in the event of the raising of the wall except to pull down the erections placed upon it, and that at the time the plans were prepared and the buildings put up the unquestioned practice under the Bristol Building Act was to allow erections such as this one to be placed on party walls. In addition to this, Dr. Grey stated that only one set of plans had been prepared, and these

had been twice shown to Mr. Watts by the defendant, and had been carefully and critically examined by Mr. Watts, who had discussed them with the defendant with a view to Mr. Watts himself erecting on his premises a similar shop, and so using the wall erected by the defendant; and that he had clearly given full consent to the user of the wall. The judge, in giving judgment, said plaintiff could not maintain any action for damages by obstruction of light, because he believed the defendant's statements as to what passed at the interviews between them; at the same time he did not think that an ordinary man could be expected to gather from the plan what use was going to be made of the party wall, and therefore on that ground he must give judgment for the plaintiff on the action of trespass, and he assessed the damages at £15, but ordered the judgment to stand over pending a suggested arrangement between the parties by which the damages would be reduced to a farthing if a deed were executed granting Mr. Watts the free use of the wall which the defendant had erected.

Cartwright Memorial Hall.—Lord Masham visited Bradford on Wednesday for the purpose of conferring with the Cartwright Memorial Hall Committee upon the tenders and designs for the new building to be erected in Lister Park, the tenders for which exceed by about £10,000 the sum of £40,000 which Lord Masham had presented to the Corporation for the erection of the memorial. It was arranged that the city surveyor (Mr. Cox) should pay a visit to the architects, Messrs. Simpson and Allen, of London, and confer with them with a view to modifying the design (without materially affecting it) in order to reduce the cost to somewhat nearer the original offer.

Improvements at Bingley.—On March 15th a Local Government Board enquiry was held into an application by the Bingley District Council for various borrowing powers. The chief of these is the erection of a new fire-brigade station in Market Street, from plans prepared by Mr. W. R. Nunns, architect, Bingley, for which £2,500 was asked. The other works included £1,000 for the widening of the Main Street at Wilsden; £500 for the sewerage of the village of Cottingley; £400 for the improvement of Park Road, Bingley, at the junction with Main Street; and £120 which has been paid in connection with the improvement of Park Road at the canal bridge. There was no opposition.

Water Under Floors.—At the last meeting of the Yarmouth Town Council the medical officer reported that he had examined fifty-eight houses in Tyrolean Square, and the walls, on every side but the south, were very damp. He had the floorings taken up, and found the "subsoil saturated with water," while in some of the houses "there were actually several inches of water under the floors, rendering the places practically unfit for human habitation and very injurious to health." A report from the borough surveyor also spoke of dwellings into which the "sun never penetrated." The Council decided to erect forthwith blocks of artisans' dwellings in Kitchener and Garfield Roads.

The Mayor of Blackpool and Jerry-Builders.—Speaking on Thursday last on the occasion of the distribution of prizes at the Blackpool Technical School, the Mayor (Dr. Kingsbury) said that their town was cursed with the jerry builder, who had a colleague with him, the plumber, whose aim was not honour but £ s. d. If there was one man more criminal than another it was the bad plumber, but the jerry-builder ran him a good second. He only hoped that the Corporation would take in hand the treatment of these persons, because if they could secure for the town honest and satisfactory building, and honest and conscientious plumbing, he was quite certain that the success of the town would be heightened and the health of the inhabitants very much improved.

Workmen's Compensation Act.—The Court of Appeal gave a very important judgment last Friday with regard to the time limit for claiming compensation under this

act. The question is, or ought to be, a simple one, says the "Daily News." The Act says that claims must be made within six months of the accident. Does that mean that legal proceedings must be taken within six months, or merely that notice of them must be given? Lord Justice Smith and Lord Justice Collins take the former view, Lord Justice Romer takes the latter. Six cases depend upon the decision, and the law lords must now decide. The County Court judges appear to have given the workman the benefit of the doubt. But the Court of Appeal in Ireland and the Court of Session in Scotland are cited by Lord Justice Smith as supporting his interpretation. If the majority of the Lords Justices are right, the workman may be put out of time, and out of Court, by the default of his solicitor. The workman himself, or some member of his family, can always give notice, and for that purpose six months is not an unreasonable time. But the technical commencement of litigation is not under the plaintiff's exclusive control.

Keystones.

The Will of the late Mr. W. H. Picton architect and surveyor, of Liverpool, has been proved at £16,741 11s. 6d. net.

A Statue of Sir Thomas Browne, the author of "Religio Medici," is proposed to be erected in the Haymarket at Norwich.

A proposed Smallpox Hospital for Manchester, to cost £60,000, was the subject of a Local Government Board enquiry held last week.

At St. John's, Macclesfield, a stained-glass window is to be erected in memory of the late Mr. C. G. Killminster, who was the architect of the church.

New Baths at Stourbridge are proposed to be built at a cost of £5,000. A Local Government Board enquiry was held last week.

Southwell Cathedral.—It has been decided to introduce new prebendal stalls at the entrance to the choir of Southwell Cathedral. The cost is estimated to be between £900 and £1,000.

New Co-operative Stores at Consett, Durham, have been built in Newmarket Street at a total cost of about £10,000. The building is three storeys high, with extensive cellerage.

Magnetism in Bricks.—The "Physical Review" has a communication from Messrs. Gage and Lawrence on the magnetic properties of bricks. Brown and pressed red bricks are, it appears, more magnetic than white bricks.

A new Methodist Free Church at Armley, Leeds, has been built at a cost of £4,000 in the centre of the large working-class district which is divided by Tong Road. Messrs. Walter Hanstock and Son, of Leeds and Batley, were the architects, and Mr. Arthur Lambert, of Bramley (mason's work), and Messrs. Horsnell and Heald, of Ossett (joinery), the chief contractors.

A Kimberley Mausoleum.—Mr. Cecil Rhodes proposes to erect a mausoleum at Kimberley to commemorate the gallant men who were killed during the siege, and he is sending Mr. Herbert Baker, A.R.I.B.A., to Egypt, Rome, and Athens to study the mausoleums there. Mr. Baker is the architect who rebuilt "Groote Schuur," Mr. Rhodes' country residence at Rondebosch, after its destruction by fire.

Court of Common Council.—At last Thursday's meeting at the Guildhall a report of the Finance and Improvement Committee, submitting a plan for making London Wall 50ft. wide, was deferred until a reply had been received from the County Council as to their willingness to contribute towards the cost of widening London Wall. Arrangements were sanctioned for continuing improvements at the western end of Cheapside and Warwick Lane, at an expense of £12,000.

Change of Address.—Messrs. Henry Ough and Son, architects and surveyors, have removed from 84, St. Paul's Churchyard, E.C., to 64, Basinghall Street, E.C.

Mr. Reginald Hallward has set up a hand-press, and is printing some fanciful works, the decorative pages of which will be produced by a method which has not been applied to artistic purposes before.

The German Archaeological Institute in Athens celebrated the twenty-fifth anniversary of its foundation on March 12th. The University of Athens has decided to convoke an international archaeological congress in Athens.

Kingston Public Library.—The new public reading-room and library at the corner of Sussex Street was opened last week. The work of renovation has been done by Messrs. Ring and Sons, contractors, according to plans by Mr. W. Kaye Parry, C.E.

Re-opening of a Flintshire Chapel.—The Calvinistic Methodist Chapel at Llanerchymor, Mostyn, has just undergone complete renovation by Messrs. Sibeon, contractors, Holywell, from plans prepared by Mr. Thomas Parry, Colwyn Bay.

Sir Frederick Burton, the well-known Irish artist, died on Friday last. In 1874 he succeeded Sir William Boxall as director of the National Gallery, and his tenure of office lasted for twenty years. In 1884 his services were recognised by a knighthood.

Mr. Andrew Black has removed from Galashiels to Glasgow, where he has entered into partnership with Mr. Robert Miller, I.A., architect; business will in future be carried on under the style of Miller and Black, I.A., architects, 58, Renfield Street, Glasgow.

The Society of Antiquaries of Scotland held its monthly meeting in Edinburgh last week, when a paper was read giving an account of the results of excavations which have been proceeding during the last five years at the Roman station at Camelon, near Falkirk. The excavations were undertaken by Mr. Alexander Mackie, under the advice of Mr. Thomas Ross, architect, and the co-operation of Mr. MacLuskie, a fellow of the society; and of Mr. Mungo Buchanan, surveyor, Falkirk, who devoted his leisure to planning the details from week to week.

Bristol Society of Architects.—At the ordinary monthly meeting of this society held last week, Mr. W. L. Bernard, president, in the chair, Mr. Peter Addie, F.S.I., the city valuer, read a paper on "The Removal of the Insanitary Areas and the Management of Improvement Schemes under the Housing of the Working Classes Act." A discussion followed, and the view was generally held that the cost of building increased the difficulty of a satisfactory solution, more especially as the sound contract work of the municipality could not be done at the same low rate as inferior speculative work. The honorary secretary (Mr. H. Dare Bryan) pleaded for some alleviation of the inartistic and depressing appearance of these dwellings, even at a slight addition to the rates, and the influence of cleanliness and order on the morals of the workers was freely admitted.

The Northern Architectural Association held its annual meeting last Wednesday at Newcastle-on-Tyne. During the past year 4 members, 9 associates, and 14 students have been added to the membership. There are now 54 members, 68 associates, and 51 students; a total of 173. The financial statement showed that the year was begun with a credit balance of £32 5s. 7d., and ended with a credit balance of £54 9s. Sir Benjamin Browne distributed the prizes which had been won by the students. In the course of a short speech he said architecture perhaps combined science and art in a way which was done in no other profession. One of our old cathedrals always struck him by the high scientific ability which it showed on the part of the man who designed it, a man who knew the value of every ounce of material and how to dispose of it to the best advantage. Mr. William Glover was re-elected president of the Association, and the other officers were also re-elected.

Engineering Notes.

Electric Power Bills.—The four electric powers Bills for Lancashire, Durham, South Wales, and Tyneside have been referred to a special committee.

The New Baptist Church at Histon, Cambridge, has just been fitted with the latest improved hot-water heating apparatus by Messrs. John King, Ltd., engineers, of Liverpool.

The Cottage Hospital, Colne, is being warmed and ventilated by means of Shorland's patent Manchester stoves with descending smoke flues, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

Hopetown Bridge, Modder River.—The centre span of this bridge has been built with remarkable rapidity by Messrs. Joseph Westwood and Co., Ltd., of Millwall, E. It is 108ft. long and weighs 80 tons, and was completed in eighteen days after the receipt of the order, and eleven days after the receipt of the material. The work was carried out under Sir Benjamin Baker.

Inverness Electric Lighting.—The Inverness Town Council has accepted the tender of £21,000 of the Brush Electrical Engineering Company, London, for the introduction of electric light into the town. This amount includes everything, with the exception of the outlay for the erection and laying of the foundations of the electric station and the opening and closing of tracks in which cables are to be laid. It is understood that the work will be proceeded with almost immediately.

Electric Tramways for Brighton.—According to the Bill introduced to the notice of a House of Commons Committee on Thursday by the Brighton Corporation, an electric generating station is to be erected about three or four miles outside the town, and the power brought by cable into the borough. The tramways are to be worked by the trolley system and will form a network over such streets as the Corporation think most applicable in the first place, and next where they can afford most accommodation. It has not been thought desirable by the Corporation that any tramways should be run along by the sea front.

Nile Works.—Owing to the satisfactory manner in which the Nile works are progressing, it is expected that the foundations throughout will be finished this year. This will render possible the completion of the whole undertaking in something like twelve months short of the contract time. At Assuan another cataract has been dammed, and the construction of foundations has been commenced. The total number of workpeople now engaged is over 23,000, 20,000 being natives, of whom a large proportion are normally in great distress at this period of the year when the Nile is low. It may be added that Mr. Gow, R.A., is painting a picture of the great dam at Assuan for the forthcoming Royal Academy exhibition.

New Reservoirs for Halifax.—The Halifax Town Council are about to commence the construction of extensive new reservoirs at Walshaw Dean. Their present water supply, after allowing for compensation water, amounts to about five and a quarter million gallons per day. The new reservoirs are to be three in number, with a total drainage of 5,215 acres, and they will provide a further available supply of two and a half million gallons per day. Their construction, it is anticipated, will involve an expenditure of from £150,000 to £200,000. The length of the three new reservoirs, which will take about seven years to complete, will be one and a half miles, the largest being the centre reservoir. One great advantage of the site secured is that, being surrounded by large tracts of moorland, the Town Council will be spared the necessity of purchasing any of the adjacent land for the protection of the water supply. Messrs. Hill, of Manchester, are the engineers for the scheme. Walshaw Dean is situated above Hebden Bridge, not very far away from the present Widdop Reservoir.

AN EXHIBITION OF FINE WARE.

THE exhibits prepared by Messrs. Doulton and Co. for display at the Paris Exhibition have been temporarily arranged in their showrooms on the Albert Embankment, Lambeth.

At Paris, these art productions will be housed in a specially-designed "pavilion," measuring about 40ft. square and constructed chiefly of stoneware of a pale green tint and semi-glazed surface ("Carrara" enamel). This general tone of pale green is interrupted only by the bold frieze of coloured salt-glazed blocks in the panels over the window openings.

Inside, and on the upper walls, three panels of "vitreous fresco" will form the chief feature. The subjects are taken from Malory and are: "Sir Galahad achieves the Perilous Siege," "Sir Galahad achieves the Sword," and "Sir Galahad achieves the Sancrael." The side panels are each 5ft. 6in. long and the centre one 8ft. 6in., all being 4ft. 6in. high. The painting is made upon terra-cotta slabs in a very rich palette of colours which fire without a high gloss, thus permitting the full strength of the colour to tell. Gold may also be used to add brilliancy; it is "fired on" and burnished afterwards where necessary. These panels have been painted by Mr. J. H. McLennan, from the designs of Mr. A. E. Pierce, who is responsible also for the design of the pavilion and for all its constructional and decorative details.

Room has been found for only one example of a decorative material quite recently introduced from which much is hoped. Under the name of "Stoneware Polychrome," Messrs. Doulton and Co. have sought to carry out on a stoneware basis the method of decoration known as majolica painting. As carried out by Della Robbia and other mediæval potters, the process consisted in covering a slab or form of terra-cotta with a thin coat of an opaque white enamel. Upon this coating the paintings were executed, and on being subjected to a second firing, the painting and the enamel surface were fused into one. Majolica, however, cannot be fired to such a degree of hardness as is desirable for exterior decoration in this climate, and Messrs. Doulton's experiments have led to the preparation of a hard stoneware body and an enamel covering which can be fired at the same stoneware heat as the body itself, and in the same kilns. Paintings fused at such an intense heat as this are not likely to be attacked by the deleterious acids found in city atmospheres. The panel exhibited has for its subject the "Crucifixion." It measures 4ft. by 2½ft. The blocks on which it is painted are 3in. thick, and are intended to be built into the wall. The cartoon is a reduction from the centre one of five panels now being executed for the exterior of a mission church in Glasgow.

Within an annexe of the pavilion at Paris it is intended to erect some examples of the work of Mr. George Tinworth. The most prominent will be the large fountain in Doulton ware now arranged in the showroom. This stands 12ft. 6in. high, within a circular basin of 12ft. diameter. A large candelabrum (one of a pair) by Mr. Tinworth is also exhibited. The place of honour in the Burslem exhibit should undoubtedly be given to the Diana vase. This fine piece is nearly 5ft. high, and is formed of a special clay and glaze made by Messrs. Doulton to enable it to resist the many burnings to be undergone in its production and decoration. Modelled by Mr. Charles J. Noke in the style of the most effective period of the Renaissance, it has on each side a large panel painted in the characteristic manner of the English School by Mr. George White and Mr. F. J. Hancock, representing Eurydice and Orpheus, and, again, Orpheus enchanting the wild creatures of the rock and forest. It is richly embellished in various metals upon an embossed ivory-like surface by Mr. H. Skinner, and is in every way a fine example of the potter's art. Among the many other vases, pots, plates, &c., are some of beautiful design and workmanship, the colouring in many cases being exquisite. The exhibit altogether is worthy of the firm.

Masters and Men.

The Dundee Plumbers' Strike has been settled by the masters agreeing to keep to last year's working rules.

The Perth Masons' Strike has been settled by the men agreeing to a reduction of their wages by ½d. per hour from May 1st. Wages will now be 8½d. for hewers and 9d. for builders.

The Bricklayers employed at Ranceby Asylum, near Sleaford, struck last week for an advance of wages from 9½d. to 10d. per hour.

The Wolverhampton Building Trade Dispute has been settled by the masters granting the men an increase of ½d. per hour from April 1st. The men asked for 1d. an hour advance, and they have given way with regard to other matters demanded relating to apprentices and overtime.

The Bristol Building Trade.—Application has been made to the Bristol Master Builders' Association by the carpenters and joiners, plumbers, painters, masons, bricklayers and labourers for sundry alterations in the working rules, and a rise of wages of ½d. per hour, to take effect on June 30th. It is reported that the masters are prepared to grant the extra wage on condition the rules remain the same, having been thoroughly revised and signed by both parties as recently as 1898.

COMING EVENTS.

Wednesday, March 21.

INSTITUTION OF CIVIL ENGINEERS.—Annual dinner at Merchant Taylors' Hall, Threadneedle Street, Sir Douglas Fox in the chair. 7 p.m.

SOCIETY OF ARTS.—Mr. Samuel Rideal, D.Sc., on "The Use and Abuse of Food Preservatives." 8 p.m.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part II.)—Lecture on "Factory and Workshop Legislation as it affects the Sanitary Inspector." 8 p.m.

BRITISH ARCHEOLOGICAL ASSOCIATION.—Meeting at 8 p.m.

Thursday, March 22.

SOCIETY OF ARCHITECTS.—Mr. G. A. T. Middleton, A.R.I.B.A., M.S.A., on "The Enrichments of the Italian Renaissance." 8 p.m.

YORK ARCHITECTURAL SOCIETY.—Mr. C. M. Hadfield, A.R.I.B.A., on "The Architecture of the Fifteenth Century and Early Tudor Period."

ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Arthur Thomson, M.A., M.B., on "The Anatomy of the Human Form: The Face; Expression, Posture, Proportion, and Modifications due to Sex, Race, Growth and Decay; Proportion."

SOCIETY OF ANTIQUARIES OF LONDON.—Meeting at 8.30 p.m.

INSTITUTION OF ELECTRICAL ENGINEERS.—Meeting at 8 p.m.

INSTITUTION OF MECHANICAL ENGINEERS.—Mr. Bryan Donkin on "Observations on an Improved Glass Revealer, for studying condensation in Steam-Engine Cylinders and rendering the effects visible." 8 p.m.

Friday, March 23.

ARCHITECTURAL ASSOCIATION.—Mr. H. C. Corlette on "The Decoration of Churches." 7.30 p.m.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part III.)—Mr. W. Hunting, F.R.C.V.S., on "Signs of Health and Disease in Animals. Destined for Food, when Alive and after Slaughter. Tuberculin and Other Tests." 8 p.m.

ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Lewis F. Day on "Ornamental Design."—XII. 11.30 a.m.

GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE ARCHITECTURAL CRAFTSMEN'S SOCIETY.—Mr. Alex. Davie, I.M., on "The Practice of Measuring." 8 p.m.

INSTITUTE OF SANITARY ENGINEERS.—Examination in Practical Sanitary Science: I.—Written. 10 a.m.

INSTITUTE OF CIVIL ENGINEERS (Students' Meeting).—Mr. J. W. Cross on "The Development of the Modern Locomotive Engine." 8 p.m.

Saturday, March 24.

EDINBURGH ARCHITECTURAL ASSOCIATION.—Visit to Donibristle House and Grounds, and small house in Grounds.

DUNDEE INSTITUTE OF ARCHITECTURE, &c.—Lecture by Mr. A. M. S. Richardson, at 7 p.m.

INSTITUTE OF SANITARY ENGINEERS.—Examination in Practical Sanitary Science: II.—Viva voce. 11 a.m.

PEOPLE'S PALACE ARCHITECTURAL SOCIETY.—Visit to St. Paul's Cathedral.

ARCHITECTURAL ASSOCIATION.—Fourth Spring visit.

SANITARY INSTITUTE (Lectures and Demonstrations for Sanitary Officers: Part III.)—Inspection and demonstration at the Sewage Outfall Works, Barking, at 8 p.m., conducted by Mr. John E. Worth, M.I.C.E.

ROYAL INSTITUTE OF PAINTERS IN WATER COLOURS.—Private View.

Monday, March 26.

SURVEYORS' INSTITUTION.—Ordinary General Meeting at 8 p.m.

GLASGOW INSTITUTE OF ARCHITECTS.—Council Meeting at 2 p.m.

ROYAL COLLEGE OF ART, SOUTH KENSINGTON.—Mr. Hugh Stannus, F.R.I.B.A., on "The Historic Evolution of Applied Art: XX.—Renaissance Christian Art," 6 p.m.

SANITARY INSTITUTE.—(Lectures and Demonstrations for Sanitary Officers: Part III.)—Mr. W. F. Shaw, F.R.C.V.S., on "The Names and Situations of the Organs of the Body in Animals," 8 p.m. Inspection and demonstration at the Metropolitan Cattle Market, York Road, N., conducted by Mr. James King, M.R.C.V.S.

SOCIETY OF ARTS.—(Cantor Lecture III.)—Mr. E. Sanger Shepherd on "The Photography of Colour,"—IV. 8 p.m.

Tuesday, March 27.

ROYAL SOCIETY OF ANTIQUARIES OF IRELAND.—Evening Meeting.

Wednesday, March 28.

SOCIETY OF ARTS.—Mr. Christopher Rawson on "The Manufacture and Use of Indigo," 4.30 p.m.

New Companies.

The Waterproofing Company, Limited.

This company has been registered in Scotland with a capital of £35,000 in £1 shares to acquire and take over as a going concern the undertaking of the Waterproofing, Varnish and Wall Decoration Company, Limited.

Contractors, Limited.

This company was registered on February 21st with a capital of £30,000 in £1 shares (6,000 preference) to carry on the business of contractors for public and private works, electrical, gas, water, and general engineers, miners, &c.

Igneous Cements, Limited.

This company was registered on March 2nd with a capital of £1,000 in £1 shares to acquire the goodwill of Mr G. Baillie in the business of cement manufacturers carried on by him at Mansion House Chambers, Queen Victoria Street, E.C.

Alexanders' Stores, Limited.

This company has been registered in Scotland with a capital of £30,000 in £1 shares to acquire the business carried on at Kirkintilloch, Falkirk and Kilsyth by Messrs. Thomas and Samuel Alexander, wholesale and retail ironmongers. Registered office: 38, Cowgate Street, Kirkintilloch.

Flameless Gas Light Company, Limited.

This company was registered on February 21st with twenty members, each liable for £1, to carry on the business of gas engineers, &c. The first directors (to number not less than two nor more than five) are to be appointed by the subscribers. Remuneration £100 each per annum, and 10 per cent. of the net profits, divisible.

William Crane, Limited.

This company was registered on February 21st with a capital of £5000 in £1 shares to acquire the business carried on at Nottingham and elsewhere by William Crane, to adopt an agreement with the vendor, and to carry on the business of builders, brick, tile and pipe manufacturers, carpenters, &c. W. Crane is the governing director, and may retain office so long as he holds three-quarters of the issued capital. Registered office: Forest Road West, Nottingham.

Ford Green Brick, Pipe and Road-metal Company Limited.

This company was registered on February 21st with a capital of £1000 in £1 shares to acquire the business now carried on by J. W. Deane at Ford Green, Norton-in-the-Moors, Staffordshire, and to carry on the business of manufacturers of and dealers in bricks, tiles, drain and other pipes, pottery, terra-cotta, &c. The directors are to number not more than three; William Deane is the first. Qualification, one share. Registered office: Bellington Lane, Ford Green, near Stoke-on-Trent, Staffordshire.

Joshua Wilkinson, Jun., Limited.

This company was registered on February 28th, with a capital of £20,000 in £1 shares to carry on the businesses of manufacturers of and dealers in anvils, vices, shovels, forks, hammers, smiths' tools, brick irons, garden tools, tie irons, &c., as carried on by Joshua Wilkinson, jun., at Upper and Lower Freebodies Mill, Kates Hill, Dudley, Worcestershire; also as general engineers and iron-founders, iron and steel manufacturers, &c.; and, further, to acquire the business of engineers and metal founders as now carried on by G. H. Chrimes at Dock Forge, Dudley, Worcestershire. The directors are W. W. Wilkinson, sen., W. Wilkinson, jun., D. G. A. Wilkinson and G. H. Chrimes. Qualification, £1,000. Remuneration £152 per annum each and a percentage of the profits, divisible.

Doust Brothers, Limited.

This company was registered on February 24th with a capital of £2,000 in £1 shares to acquire the business carried on by F. H. Gregory at 199-201, Freeman Street and Wellington Street, Grimsby, and to carry on the business of painters, oil and colour manufacturers, art dealers, &c.

Heysham Hall Estate Company, Limited.

This company was registered on February 24th with a capital of £45,000 in £100 shares to acquire land and buildings in Lancashire or elsewhere, and in particular the Heysham Hall Estate, and to carry on the business of land and property owners, builders, contractors, house, land and estates agents, &c. Registered office: 49, North Road, Lancaster.

Robinson, David and Co., Limited.

This company was registered on March 2nd with a capital of £120,000 in £10 shares to carry on the businesses of timber merchants, &c., as carried on by S. Robinson and W. David at Cardiff under the style or firm of Robinson, David and Co. The first directors (of whom there shall be not less than two nor more than five) are S. Robinson and T. W. David (governing directors).

Wirral Plate-Glass Insurance Co., Ltd.

This company was registered on February 27th, with a capital of £2,000 in £1 shares to grant and effect assurances of every kind against the loss, breakage, or damage (other than by fire) of or to plate-glass and other glass of every description. The first directors (to number not less than three nor more than seven) are W. Atherton, W. T. Brick, E. A. Evans and T. F. Jones. Qualification, 50 shares.

Grove and Company, Limited.

This company was registered on February 24th, with a capital of £7,500 in £10 shares to acquire the business now carried on under the firm of Grove and Co., and to carry on the business of potters, brick, tile and glass makers, stone and flint grinders, &c. The first directors (to number not less than three nor more than five) are C. Wedgwood, F. H. Wedgwood, K. L. Wedgwood and J. Shuffelbotham, each of whom may retain office as long as he holds £250 shares.

Cwm Building Company, Limited.

This company was registered on February 24th, with a capital of £10,000 in £10 shares, to adopt an agreement with G. H. Rosser, Walter Rosser, G. Rosser, Mary H. Johnson and J. Rosser, and to acquire and deal with any lands, buildings, quarries, plant, or other property. The first directors (to number not less than two nor more than seven) are F. Mills, J. F. Tallis, J. R. Jacob, J. Stanfield, E. Phillips, J.P., and A. Johnson. Qualification, ten shares. Registered office: Westgate Chambers, Newport, Mon.

Tramways and Light Railways Estates Company, Limited.

This company was registered on Feb. 25th with a capital of £100,000 in £10 shares, to purchase, take on lease, or in exchange, lands, buildings, &c., or any interest therein, and to develop, deal with, and turn to account the same, building thereon; to deal in and with freehold and leasehold ground rents; to make advances upon the security of lands, buildings, or other property; to establish and maintain gas, water and electric supply works, sewerage works, &c.; to construct and maintain rail and tram roads, wharves, docks, piers, warehouses. The signatories (each one share) are:—G. Morse, G. Stevens, T. Vickers, C. H. Dade, E. Hopwood, G. J. Somerville and E. Garcke. The first directors (of whom there shall be not less than three nor more than six) are to be elected by the signatories. Qualification, £25. Remuneration, £50 per annum each, and a percentage of the profits, divisible; maximum, £2,500.

Anglo-Belgian Fireclay Company, Ltd.

This company was registered on February 28th with a capital of £15,000 in £1 shares to acquire certain concessions granted to Mr. G. T. G. Merckens for getting and working kaolin or china clay and sand on and under lands situate at St. Gerard, Belgium. The directors (to be not less than three nor more than seven) are H. A. Northey, A. E. Young, Major J. R. Scott, F. Haack and G. T. G. Merckens, Qualification, 250 shares. Remuneration £200 per annum, divisible.

Wouldham Cement Company (1900), Ltd.

This company was registered on Feb. 24th, with a capital of £250,000 in 10,000 preference shares of £10 each and 150,000 ordinary shares of £1 each to acquire the business carried on by the Wouldham Cement Company, Limited (incorporated in 1865), and the business carried on by S. Pearson and Son, Limited, at the Lion Cement Works, West Thurrock, Essex, and to carry on the business of cement and brick manufacturers. The number of directors is to be not less than three nor more than seven; the first are John Bazley-White (chairman), Sir Weetman D. Pearson, Bart., William Morgan and Ernest E. Pearson. Qualification, £1000. Remuneration, £1000 per annum, divisible. Registered office: 35, Great St Helens, E.C.

TENDERS.

Information from accredited sources should be sent to "The Editor." No results of tenders can be accepted unless they contain the name of the Architect or Surveyor for the Work.

BURSLEM.—For the erection of laundry, &c., Chell, for the Wolstanton and Burslem Guardians. Mr. W. H. Walley, architect, Queen-street, Burslem. Quantities by architect:—
W. Cooke ... £1,854
Bennett Bros. ... 1,700
York and Goodwin ... 1,626
J. H. Ford ... 1,616
C. Smith ... 1,599

GATESHEAD.—For the erection of a rectory, St. John's, Gateshead Fell, for the Rev. J. Mitchell. Messrs. Joseph Potts and Son, architects, 57, John-street, Sunderland. Quantities by Mr. J. C. Christon, 57, John-street, Sunderland:—
J. B. Stott ... £2,798 9 10
J. Bewley ... 2,623 0 0
Henderson and Wakefield ... 2,008 0 0

GLoucester.—For the erection of two shops and offices, &c., Southgate-street, for the Corporation. Mr. Alfred J. Dunn, A.R.I.B.A., architect, 31, St. Michael's square, Gloucester. Quantities by Messrs. Vale and Kingsford, Gloucester:—
Bailey and Dean ... £5,500
H. A. Forde and Sons ... 5,460
W. T. Nicholls ... 4,780
W. Jones ... 4,590

LONDON.—For the construction of public conveniences, Broadway, Ealing, for the Urban District Council. Mr. Charles Jones, C.E., Public Buildings, Ealing:—
L. Macklin ... £5,500
Clift Ford ... 2,391
Neave and Son ... 1,940

Grant and Sons ... £1,590
C. W. Machin ... 1,498
J. Cooke ... 1,490
J. J. Longden, Burslem (accepted) ... 1,460

Draper and Son ... £2,450 0 0
W. Hall ... 2,311 12 2
R. & J. Stephen-son, Low Fell ... 2,197 0 0

* Accepted.

T. J. Williams ... £4,422
A. and A. E. King ... 4,247
Collins and Godfrey, Tewkesbury* ... 4,058

A. and A. E. King ... £1,734
Thomas and Edge ... 1,674
Dickens, Ealing* ... 1,507

* Accepted.

HENDON.—For erecting the "Railway Tavern," Mill Hill, Hendon, for Messrs. M. A. Sedgwick and Co., the Brewery, Watford. Mr. Charles P. Ayres, architect, 14, High-street, Watford:—

Wall and Co. ... £3,739
Watman ... 3,656
Coleman ... 3,644
Mead and Burton ... 3,618
Turner, Limited ... 3,550
Dove ... 3,395
Webster and Cannon ... 3,348
Wilson, Limited ... 3,342
Patman & Fotheringham ... 3,271

LOUGHBOROUGH.—For the construction of an impounding reservoir of a capacity of 510 million gallons in the Blackbrook Valley, comprising a masonry and concrete dam 48ft. in length and 10ft. in height from foundation to top of parapet, and all appurtenant works in connection therewith. Messrs. George and F. W. Hodson, engineers, Westminster and Loughborough:—
L. P. Nott ... £24,812 10 2
J. F. Price ... 80,186 10 0
Joseph Tomlinson ... 77,711 11 11
George Lawson ... 77,513 0 0
Kellett and Co., Ltd. ... 74,816 8 2
Thomas Stewart ... 74,589 0 0
Nowell and Co. ... 73,017 5 3

MILFORD HAVEN.—For additions to schools, Great North-road, for the Steynton (U.D.) School Board. Mr. D. Edward Thomas, architect, Victoria-place, Haverfordwest:—
Davies and Son ... £1,328
Robert Cole ... 1,327

CONTRACTS OPEN.

TO BUILDERS and CONTRACTORS.

The Guardians of the East Retford Union, Notts, invite TENDERS for the ERECTION and COMPLETION of new WORKHOUSE INFIRMARY, Retford. Drawings and specifications may be seen on and after MONDAY, MARCH 12th, at the office of Messrs. EYRE and SOUTHALL, Architects, Chapelgate, Retford.

Bills of quantities will be supplied to builders on receipt of a deposit of £2, which will be returned if a bona-fide Tender is submitted.

Sealed Tenders, endorsed "Workhouse Infirmary," to be sent in to the undersigned on or before MONDAY, MARCH 26th.

The Guardians do not bind themselves to accept the lowest or any Tender.

THOS. WM. DENMAN,
East Retford, Notts, Clerk to the Guardians.
March, 1900.

EDMONTON SCHOOL BOARD.

TENDERS are invited for the ERECTION of new SCHOOLS at Bowes-road, N.

Persons desirous of tendering must send in their names to the undersigned not later than MARCH 19th, accompanied by a £5 Bank of England note, which will be returned upon the receipt of a bona-fide Tender.

The plans and specification, prepared by Mr. H. W. DOBB, of No. 54, London-wall, E.C., may be seen at his office during the usual office hours, and copies of the bill of quantities (by Messrs. YOUNG and BROWN, 7, Southampton-street, Bloomsbury-square, W.C.) will be forwarded on application.

The contract will contain the ordinary trades' union clause as to hours and wages, and the successful contractor will be required to enter into a bond with two sureties for the proper execution of the work.

Sealed Tenders, endorsed "Bowes-road School," are to be delivered to the undersigned not later than NOON, TUESDAY, APRIL 3rd, 1900.

The Board do not bind themselves to accept the lowest or any Tender.

School Board Office,
Brettenham-road,
Upper Edmonton,
March, 1900.

JOHN MOULE,
Clerk to the Board.

COMPETITIONS.

ADMINISTRATIVE COUNTY of the ISLE OF WIGHT.
TO ARCHITECTS.

The Technical Education Committee of the County Council of the Administrative County of the Isle of Wight invite DESIGNS for a BLOCK of BUILDINGS, comprising a Public Library and Reading Room, Technical Institute Offices, Caretaker's Residence, &c.

A lithograph plan of the site, with sketch showing approximately the accommodation required, and instructions to competitors, will be forwarded on application to the undersigned.

The cost of the buildings is limited to about £6,000.

Premiums of Fifty Pounds each will be given to the authors of the two Designs considered by the Committee as the first and second in merit, which designs will become the property of the Council. The author of the Design considered the best shall, if required by the Technical Education Committee of the County Council, furnish the necessary contract drawings, with details, and specification, for the purpose of obtaining Tenders to execute the works, for which, if so required as aforesaid, he will be paid 2½ per cent. on the estimated cost.

If employed to superintend the works such 2½ per cent. and the premium of Fifty Pounds to merge in the usual architect's commission of 5 per cent. on the cost, which shall include the necessary detail drawings, copies for

contractor and clerk of the works, superintendence, and all expenses.

All designs to be sent, in accordance with the instructions, to the undersigned on or before APRIL 30th, 1900.

WILLIAM H. WOOLDRIDGE,
County Council Offices, Clerk to the County Council.
Newport, Isle of Wight,
February, 1900.

TO ARCHITECTS.

The Governors of the Bury Grammar Schools invite Architects to submit COMPETITIVE DRAWINGS for NEW SCHOOLS proposed to be erected within the County Borough of Bury, at a cost not exceeding £17,000.

Premiums of £100, £60, and £30 will be awarded for the designs adjudged of sufficient merit and placed first, second, and third in order, respectively.

The Governors will be advised by a competent Assessor in the selection of the drawings.

The premiated drawings will become the property of the Governors.

Lithographed plan of site and copy of conditions may be obtained on application to J. CARTWRIGHT, M.Inst.C.E., Peel-chambers, Bury, on payment of a deposit of One Guinea, which sum will be returned on receipt of Competitive Drawings.

Drawings to be deposited at my Offices, in Broad-street, Bury, by JUNE 1st, 1900.

S. WOODCOCK,
Clerk to the Governors.

EFFINGHAM HOUSE,
ARUNDEL STREET,
STRAND, W.C.

An Architectural Causerie.

An Architect's Spare Moments.

EVEN in the busiest offices there are periods of comparative dullness, when the problem of how the time is to be profitably occupied becomes unpleasantly obtrusive. If the staff be large, the temptation is often to reduce it, when the solution of the problem is transferred from the architect to his dismissed assistant, with whom it is just as pressing and possibly more difficult; while, where the staff is already as small as prudence will justify, the necessity of employing every member of it fully in order to prevent "slackness" and want of discipline is very real. In circumstances like these the architect has one great advantage over members of other professions, in that there is almost always a competition upon which he can exercise his own skill and that of his assistants, not only preventing their getting rusty, but with the probable result of general improvement all round. Yet there are many ways in which an architect, whose most strenuous efforts are necessary in order to earn a bread-and-butter living, can more profitably employ his leisure than in competition work, with its problematical success. Those with any literary skill ought to have little difficulty in disposing of articles upon technical subjects, especially if they commence by approaching the editor whom they think likely to accept their work with a list of suggested subjects; and the writing of technical articles for the technical press may readily expand to writing as a specialist for the general press, or to the publication of technical books. Similarly, the man who is possessed of the gift of pen draughtsmanship can usually, with a little perseverance and the exercise of that class of tact which would prevent him from sending an illustrated joke to "Good Words," obtain fairly remunerative employment for odds and ends of time. [Not very often, we fear; this particular market is overstocked. —Ed. B. J.] More legitimate still, perhaps, because more akin to an architect's true vocation, is the preparation of designs for the fittings and finishings of buildings, wall-papers, furniture and textiles, for which there is an unlimited demand so long as the work be good, and the trained architect has many advantages in the race of excellence. Quite another field again presents itself to the man who decides to employ his spare moments in increasing his connection and impressing his friends with his knowledge of his profession. Many attempt to do this by aiming at social success, but this is a risky proceeding, better replaced by reading papers before local archaeological societies and delivering courses of lectures at a nominal fee (it rarely answers to give free lectures) upon some such popular subject as constructional hygiene. A large amount of kudos, even

locally, is to be obtained by reading a paper before the architectural society located in the nearest large city, and even more if it be accepted by one of the great Metropolitan societies who, for their part, are often seeking original matter and new men, and would be only too glad to be approached by anyone with something fresh to say. This sort of thing may not have an immediate money value, may even involve a certain amount of expense, but it goes a long way to make or sustain a reputation, and it is questionable whether in the long run it may not do more good than work for which immediate payment can be obtained. G. A. T. M.

nating in spires, was inaugurated by William the Conqueror in 1056, and is one of the finest specimens of ecclesiastical architecture in Normandy. Coutances is the ancient Roman Cosedia in the country of the Unelli, and many traces of Roman work are still to be seen in its environs.

Colourless London. LONDON, though the largest and most opulent capital in the world, is singularly lacking in some of the attributes of smaller

LANTERN, CENTRAL TOWER, COUTANCES CATHEDRAL. DRAWN BY J. A. WOORE.

Coutances Cathedral.

THE illustration of the lantern in the central tower of Coutances Cathedral which we give on this page is from a pencil drawing by Mr. J. A. Woore, and is one of a set which received a medal of merit in the R.I.B.A. Pugin competition this year. The town of Coutances is built on a granite ridge which rises between the canalised River Soule and the stream called the Bulsard, sixteen miles from St. Lô and seven miles from the sea. The cathedral of Notre Dame on the height, with its two lofty towers termi-

and far less important cities on the Continent and elsewhere. It may be considered as the most colourless and, with the finer, more central portions excepted, the dingiest mass or "province of houses" in Europe. Thanks to modern enterprise and advancing architectural taste, the important parts of London can boast of some fine buildings, such as the Imperial Institute, New Scotland Yard, &c.; also many other new buildings of an entirely commercial character where colour is being carefully and tastefully introduced by means of terra-

cotta, red brick, mosaic work, and coloured plaster, as in several new premises in Oxford and Regent Streets. But with regard to the less important parts and the suburbs—those endless ramifications of "Greater London"—nothing can exceed their stale monotony, dreadful colourlessness, and general depressing hideousness. Take almost any rising suburb; of what does it mainly consist? and how does it come into being? What were fields and hedgerows become long strings of monotonous boxlike villas all of one pattern, and where any colour is attempted it consists of a vulgar use of crude red brick and tile, with false ornament stuck on in a meaningless manner to proportionless walls and gables. If we are a practical nation, "A nation of shopkeepers," why should we allow such a refinement of ugliness? The only answer is that cheapness is the main consideration. But surely it is as easy and as cheap to do without sham ornament and unnecessary stone embellishments, and in their place to aim at proportion, taste, and judiciously applied colour. Would it be absolutely curtailing the "liberty of the subject" if some control were exercised architecturally as well as structurally upon new erections? Why not even have a Ministry of Fine Arts, as in Paris?

The peculiar colourlessness of London arises partly from the smoke-laden atmosphere, partly from its natural climate, and partly from the indifference of the average citizen to all matters architectural. The predominant "note" of the London streets is a dull leaden grey, which pervades pavements, roadway, house fronts and roofs, the only touches of colour proceeding from the omnibuses, pillar-boxes, or garish advertisement hoardings. Few prospects equal in gloom that of a London street, suburban or otherwise, when seen on a dull Sunday. Is there any feasible means of remedying or modifying this state of things? Without indulging in any Utopian dream, it would seem that there might be a remedy, though as long as the London atmosphere is saturated with smoke it will be a difficult task. Kiosques are useful and cheerful objects, and might be much used in the principal thoroughfares as in Paris. In summer, why not make more use of properly coloured awnings—buff or a good green instead of the usual dingy drab things. Tinted tiles could be more used in addition to the terracotta so much in vogue, though unless tiles are most carefully employed and are of a good tint the effect on buildings is very crude and glaring. An immense field for the display of colour would be the advertisement hoarding, often so terribly hideous, though its hideousness is totally unnecessary, as some very good recent posters testify.

Lastly, for summer purposes many flat roofs and parapets might be decked with flowers and plants and utilised as open-air cafés and for smoking; here people might sit removed from the turmoil of the street and enjoy a modicum of fresh air. If these roof-gardens were properly designed, and unpleasant views of chimneys were hidden by shrubs and plants, they would soon become popular resorts. In several ways London might well take a lesson from Paris, Brussels, and other Continental cities. Because we live in a gloomy climate that is no reason why we should meet the climate halfway in gloominess. Much has been done by modern architects to impart colour into London streets by using terra-cotta and red brick instead of the liver-coloured brickwork of forty years ago, but much more remains to be done before London becomes a "City of Light," or a feast of colour.

C. S. B.

On Reflection.

Artistic Copyright. ANYONE who has had to do with the existing law about artistic copyright knows what chaos here exists, and it is to remedy this state of things that Lord Monkswell's Bill has been drafted. Whenever a multitude of enactments govern any particular subject, it generally follows that the exact law is very difficult to define, owing to the cross-references which seem somewhat to clash with one another. Artistic copyright is governed by no fewer than ten Acts, the first being passed in 1734 and the latest in 1886, and each appears to have been drawn up without much consideration for those that preceded. The result is that nobody can determine exactly where copyright begins and ends. These laws divide the subject into three classes—engravings and prints, sculpture, and paintings and photographs—each of which is subject to certain exclusive restrictions. For instance, you cannot copyright engravings and prints in Great Britain unless they are actually made here; sculpture and paintings and photographs can be made here or in the colonies, but the first must be published in this country in order to obtain copyright, and the two last must be made by a British subject, or a person living on British soil. It need hardly be pointed out that this division of the copyright law is very ridiculous and unnecessary. Then as to the duration of copyright. Engravings and prints enjoy it for twenty-eight years after publication; sculpture enjoys it for half that term (with a second term of fourteen years if the sculptor survives the first); and paintings and photographs enjoy it until seven years after the artist's or photographer's death. Under the present law an artist loses the copyright in his picture if he sells it without having a written statement from the purchaser that the copyright is vested in the artist; yet the purchaser cannot claim the copyright unless it is directly assigned to him in writing by the artist. If neither of these two things is done, nobody gets the copyright, and the picture may be copied by anyone who is smart enough to get hold of it. If Lord Monkswell's Bill is passed (and we sincerely hope it will be) the copyright will rest with the artist, unless he assigns it in writing, and all kinds of artistic work will receive the same protection for the same term—namely, the artist's life and thirty years afterwards.

The Sculptor-Architect.

It is constantly deplored that we have few works erected at the present day that are worthy of a high place in the history of architecture, and in a like degree that we have few good works of sculpture that are architectonic. Yet we do not attempt to repair this deficiency. It is not that a way has not been found to get out of this nor that history affords us no hint to aid us in the endeavour. It is hardly going a point too far to say that all architecture in the past was the work of sculptors—we have but to refer to the Egyptian, Grecian and Roman, Indian, Japanese, and Gothic as examples. And when we study the greatest works known to us we see the special value of a practical knowledge of sculpture; the Parthenon would have been nothing without a Phidias; the Argive Heraeum nothing without a Polyclitus; and the works of Michaelangelo, Giotto, Donatello, Niccola Pisano and other Renaissance architects testify to the value of a training as a sculptor. The greatest example of this sculptural training is to be found in Gothic work, where in all the great periods the architect was always and necessarily a sculptor, or, as sometimes referred to in

those days, a "master mason." We are quite prepared to admit that at the present time it is not generally possible for the architect to personally execute his own sculpture, nor that it is a necessity in the production of every architectural work that he should be a sculptor; but we do contend that a training in this art is necessary for the production of great works, such as those of a monumental character. It may be contended that this is all very well for those who hope to have the designing of these great works given to their hands, but those who merely aspire to the erection of commercial and domestic premises do not require it. But after all architecture is, broadly speaking, merely sculpture—a due regard to proportion, mass, solids and voids, and rhythm—and the study and practice of sculpture will aid the faculties in the exercise of these qualities; and added to this is the benefit that may be derived from the study of nature and the human form and the help in affording a ready means of seeing the actual effect of a piece of carving, or the appearance of the structure itself, by a clay model. There is also something to be said for the contention that the greatest pleasure to be derived from a building is to read the sculptures, as archæologists do now, and so penetrate the very thoughts of the makers. Sculptors nowadays are inclined to produce statues—life-size or miniature—in their studios, for sale as separate pieces of furniture, as it were. Now, although the Greeks gave us the statue in this form, we do not find them untrained in the architectural use of sculpture. Everywhere we see in modern work this want of architectonic sense in sculpture, not only on buildings but in statues, which are set up without any regard to their surroundings. We require more sculptors like the late Harry Bates, A.R.A., whose work at the Institute of Chartered Accountants is a standing example of the co-ordination of sculpture and architecture.

Well Done! It is gratifying to know that there are enough public men and pressmen who have a sense of fitness and artistic feeling sufficient to compel the abolition of many new-fangled ideas of the advertiser for giving further publicity to his wares and helping to destroy what beauty in our streets still remains. It is not so very long ago that the ugly sky sign was ordered to be pulled down, and now the London County Council has prohibited the use of those flash-lights and night-signs (more particularly the latter) which have been so long an eyesore. Mr. Charles Whibley said of these night-signs in a recent number of a contemporary:—"They wink, they shift, they scintillate, they go out. Now yellow plays on red; now darkness pockets all the colours; and the passer-by is not only distressed by these sudden apparitions, he is even prompted to the cultivation of a new vice. As his cab rushes by the illuminated spot he will hazard all the money in one pocket against all the money in another that the red light will not flash again until he is swept off out of sight." This is light criticism, but it covers a great truth, which is that these forms of advertising are outrageous to public taste (however indefinite a quantity this may be). The exact wording of the Council's by-law is somewhat ambiguous, for it says that no flash-light (this includes all those illuminated letters, signs, and devices which we know so well) or search-light shall be visible from the street and "cause danger to the traffic therein." The word "street" includes, however, everything that can possibly be called by that name, while the provision about causing danger to the traffic has, we assume, a similar wide bearing; so that it really seems that these signs and lights are to be stopped—and a good thing, too.

LANCASHIRE CHURCH ARCHITECTURE.*

By W. H. B.

THOSE who know the architectural annals of the County Palatine may well ask "can any good thing come out of Nazareth?" The ruins of its religious houses are few, and are not in any sense remarkable. If we compare Furness with Fountains; Whalley with Rievaulx or Whitby; and Cockersand with Guisborough or Easby, we shall see how much richer in these relics is Yorkshire than the western shire with which, to such a large extent, it is coterminous in boundary. Nor has Lancashire any churches like St. Mary's at Beverley; the Grey Church at Old Malton; St. Mary's, Hull; Wakefield Cathedral; or the "Old Churches" at Bradford or Halifax. Yet it was in Lancashire, to a great extent, that the Gothic revival had its origin. Authorities generally admit that in his "Attempt to Discriminate the Styles of English Architecture from the Conquest to the Reformation, with Notices of Eight Hundred English Buildings," Thomas Rickman, a Liverpool architect, led the way in that revolution in art which has largely sought to realise the dreams and ideals of writers so diverse as Walter Scott, John Mason Neale and Bulwer Lytton. Rickman published his work so early as 1817, and so well and conscientiously had he done his part that a second edition was soon called for. At the time of the publication of his first edition, it is well to note, the younger Pugin was only six years old. A short extract from his preface explains his motif. "The object of the present publication," he says, "has been to furnish, at a price which shall not present an obstacle to extensive circulation, such a view of the principles of Architecture, more particularly that of the British Isles, as may not only be placed with advantage in the hands of the rising generation, but also afford the guardians of our ecclesiastical edifices such clear discriminative remarks on buildings now existing as may enable them to judge with considerable accuracy of the restorations necessary to be made in those venerable edifices that are under their peculiar care; and, also, by leading them to the study of such as still remain in a perfect state, to render them more capable of deciding on the various designs for churches in imitation of

the English styles, which may be presented to their choice."

The little work realised all and more than Rickman had anticipated for it, so that we have one more illustration of the superiority of genius to its particular environment. In his enumeration of buildings, which forms the appendix to his work, Rickman traverses every English county for his examples of styles. Only nine of these examples, however, are furnished by his own county, and necessarily he draws on Yorkshire, Lincolnshire, Oxfordshire, Warwickshire, Nottinghamshire, and Norfolk for his fullest lists. We wonder if he was struck, as we have frequently been, with the poverty of the examples close at hand? Nearly every parish church in Lancashire—speaking, of course, of the ancient buildings—

is of one era and one type. That type is the late perpendicular, of which we have a familiar example in Ribchester, leaving out the earlier chancel and the strange, modern clerestory dormers.

Ribchester is an old historic centre, dating back to Roman times, and, in consequence, we find at Ribchester what is rare in other Lancashire churches—features of all the styles. The chancel is a "deep" one, and at one time was undoubtedly pure Early English. It has been restored, with the usual bad effects of early restorations. In an old side chapel in the north aisle there is a fine flamboyant window, which makes quite a picture when seen through the foliage from the vicarage garden. The stone tracery is complete, but nearly the whole of the old glass is gone, except a piece in the upper foliation which portrays our Lord in Glory. Whalley (where there is some excellent choir carving), Leyland, Higher Walton, Great Harwood, Guisburn, all are churches of the Ribchester type, only poorer in character and more uniformly of one style. They consist as to plan of western tower, nave, north and south aisles, and deep chancel. The only example we know of a cruciform church is furnished in Cartmel.

The drawing of Whalley Church on this page is from the facile pen of Mr. Herbert Railton.

But the poverty of the great cities is even more remarkable than that of the towns and villages. Manchester retains its "Awd Church" in its splendidly-restored cathedral; that is the one ancient ecclesiastical building of which it can boast. Liverpool is all modern. Burnley Parish Church should be an ancient structure, but it is a thing of shreds and patches, and has been rearranged out of all semblance to its former self. How unlike the big towns across the Pennine Chain, such as Bradford and Wakefield, Hull and Halifax. Some day, perhaps, some thoughtful writer will sit down and answer for us two important questions. How is it that Lancashire exhibits such lack of ecclesiological endowment; and how has it come about that nearly the whole of its churches are of one style of architecture, and have evidently been erected or re-erected at about the same period? We know from Domesday, that the country was, in Norman times, thinly populated and very poor. Then, when it attained the dignity of a Palatinate, it lived a life apart from the rest of the English shires and had an internal economy "all its own." Its duke was a king in all but name. He could

DRAWN BY HERBERT RAILTON.

ST. MARY THE VIRGIN, LEIGH.

pardon treasons, murders, and felonies. He held a separate Court of Chancery, Court of Common Pleas, and Court of Criminal Jurisdiction. He could summon his own barons, and the King's Writ did not run in his dominion. Did Lancashire suffer architecturally from its being outside the regular stream of our national life until the reign of Henry the Fourth? Or are we to put down its poverty until quite recent times as the main factor in its architectural leanness? It is a pity that the ordinary Lancashire manufacturer is a man of limited education, whose principal endowment is a prehensile faculty of money-getting. He is, however, improving, and as the standard of taste rises in a backward county we may in time come to see more buildings of the character of that splendid church at Stockport, of which such excellent illustrations were given in Vol. I of the "Architectural Review." If the big towns of Lancashire have, unhappily, remaining in them few relics of the art of ancient days (in towns like Preston and Blackburn hardly a stone of ancient work is anywhere to be traced), the man of culture and the conscientious architect may well unite in the determination that such new buildings as are erected shall in some way harmonise with ancient and true canons of art. Much has undoubtedly been done since Rickman's time. A handsome Roman Catholic church at Lancaster; a new English church at Morecambe; the fine new church of St. Silas's in Blackburn; and new country churches like that of Hapton, are indications of the trend of public taste as well as professional proficiency. Even the architects themselves are becoming more severely critical of their own work. For an example of this we need only compare the Church of St. Mary the Virgin, Leigh, by Messrs. Paley and Austen, with their most recent work in St. Silas's, Blackburn. In the early years of the Gothic revival some excellent churches were built in Lancashire, some by Rickman himself and some by architects who followed his careful leading. They were marred, however, by short chancels, as at Mellor, Holy Trinity, Darwen, and in Blackburn Parish Church. The latter is a really fine building structurally considered, but as it was built in the early

THE CHANCEL GABLE IN ST. SILAS'S CHURCH, BLACKBURN.

twenties it is naturally faulty in many of its features. Pleasington Priory, the façade of which is illustrated on the opposite page, is a church belonging to the Roman Catholic body, and shows how early most elaborate attempts were made to improve the character of the prevalent styles, or rather the absence of them. This edifice was erected in 1816-17. John Palmer was the architect, and Thomas Owen the sculptor. John Palmer was also the architect of the Blackburn Parish Church, which is of quite cathedral-like dimensions.

These brief notes on a large subject may well be closed with the reflection that with Lancashire it is the day of opportunity. Manchester is rightly enlarging, improving and enriching its somewhat diminutive cathedral. Liverpool may, some day, have a cathedral which, as a structure, may not be a reflection on the wealth and commerce of the second city of the Empire. The Gothic revival might in this way be fitly honoured in its birthplace. It is better that we should "bide a wee" than, in the hurry to attain a desired end, we should erect a building unworthy of the recovered knowledge we have obtained of the ancient English styles.

PUBLIC BATHS AND WASH-HOUSES.*

BY A. SAXON SNELL.

I DESIRE first of all to remind you of a few cardinal points which I venture to think cannot too often be reiterated, and some of the most trite and obvious might with advantage be pressed upon those public authorities who have the inception and carrying out of these institutions.

Firstly as to sites. It has been pointed out that irregular sites with small frontages can be advantageously used for public baths. With the exercise of considerable ingenuity and a lavish provision of corridors it may be so. Nevertheless, it is certain that what is gained in economy in the cost of the site is lost in inferior arrangement, long lines of communication and wasted space. It is one of those "ways out" of a difficulty which is best spoken in the ear of a client in real difficulties for a site at all. Let us beware of the authorities coming to the conclusion that any site is good enough for public baths. Public institutions of most kinds should occupy positions of honour in our towns—entirely surrounded by streets if possible, always at least detached from other buildings. We have yet in Britain to learn this lesson from any third-rate German town.

Secondly, as to the general arrangement of the buildings. It is well for us to remember that the more completely a building is planned, the easier, and, therefore, the more economical will be its management. And it is not the first cost so much as the annual charge for management and maintenance which makes public baths, as a rule, unremunerative. I use the term "unremunerative" in the narrow sense of the word, meaning that these institutions seldom yield a direct monetary profit upon the outlay and expenses. Will you pardon me if, upon this subject, I quote a few paragraphs, with some variations, from my last year's paper? (This paper was published in the BUILDERS' JOURNAL for March 8th and 15th, 1899.)

"The word economy is brought into contempt so often by its misuse in the mouths of narrow-minded people with whom it is synonymous with 'cheapness,' that it is worth while to define our interpretation, the short form for which is arrived at by labelling it with the words 'wise' or 'true.' In planning a building, then, to ensure or make possible 'wise' or 'true' economy in administration, we mean arranging the various parts in such order as will enable those who administer it thereafter to do so with the least waste of human energy; and the architect is fortunate

whose clients perceive the true bearing of this principle. It is only just to them, by the way, to say that it is largely recognised to-day, as witness the lavish expenditure upon glazed bricks, majolica, and other surface decorations, the great first cost of which is so soon repaid by their permanence and the small cost of maintenance. I need scarcely remind you that we as architects are much more interested in the first cost of a building than its subsequent maintenance; and it is, therefore, also our interest to build well from the first. That is, by the way; it does not benefit us alone. Indeed, our share is, comparatively speaking, small; the benefit to our client, far greater. For it is obvious that if by our skilful planning we make it possible to administer a building with five servants, say, instead of six, we save our clients a subsequent expense, to take a low estimate, of £60 annually—a sum which, capitalised, could be expressed in buildings to the value of £1,800, or thereabouts. Inversely, if by spending an additional £800 our client saves the cost of one servant, he is the gainer of £1,000.

"For some years our rulers have been slowly

THE CHANCEL OF ST. GEORGE'S CHURCH, STOCKPORT.

learning the lesson which generations of architects have endeavoured to teach them, but they listened not to our voices, and have even hinted that we advocated magnificence in our public buildings for purely personal reasons. Judged, however, by modern buildings, I think they begin to realise that money spent in buildings is not spent in the sense that it leaves the community poorer, but rather that it is *invested*. It is beginning to be understood that in no way can money be more widely circulated, or give a better return to the community, than in building. It is recognised that nothing is more educational to the lower stratum of human life than to house it decently, and to accustom it to better surroundings. The money spent in public buildings must be regarded as invested only—and well invested. A little sign that the public are beginning to perceive this is afforded by the growing tendency in competitions not to hamper the competitors by a fixed price. May the tendency grow into custom! Another is the trouble our authorities take in visiting other institutions to learn what is best in them, and then to go one better. The younger generation of architects have a good time before them if we foster the growing imagination of our clients to lead them on to yet higher ideals, yet nobler efforts."

It is to architects they will look, as in the main they always have looked, to give that lead which was never more wanted, and, happily, never more appreciated, than to-day.

The very first essential in any building is the plan, and personally I wish that this

* A paper read before the Liverpool Architectural Society on March 5th, 1900.

CHURCH OF ST. MARY, CARTMEL.

obvious truth was more thoroughly insisted upon than it is in architectural education. We have our classes for construction and design. Why not for planning? In public buildings, the simpler and more direct the plan, and the greater the proportions between the rooms and passages, the better. Unless a passage reaches the proportions of a gallery (when it can be used as such), or is small enough to be regarded as a lobby, it is so much waste space which has to be paid for in first cost, and subsequently maintained and kept clean at further expense. This is applicable to public buildings in general, but it is our business now to discuss public baths in particular. Under this head are included swimming, washing, and Turkish baths, and all of them until late years have been combined in one building for economy of administration, and I suppose for a certain sense of fitness.

It is obvious that few towns and boroughs can afford several sets of baths; and one establishment, however centrally placed, is likely in most cases to be a long distance from the greater part of the population. The desire for cleanliness is not, I fear, so strong among those who need it most to induce them to walk a mile or two for the opportunity of a bath; and latterly a wise experiment has been made in the distribution of small sets of washing baths in the various quarters of the municipal area, and with very encouraging results. In time it may be possible also to multiply the number of swimming baths in these areas, but not, I fear, for many years yet. The British public learns very slowly, but, happily, very surely.

I should much like to enlarge upon this subject of the proper distribution of baths, but save in shortly prefacing my remarks upon washing baths, I shall not pursue it further. My paper is not addressed directly to public authorities with whom these matters rest. Speaking to a body of architects, it is perhaps more of interest to deal with the buildings themselves, and my only reason for referring to the question of their distribution is that we should have some ideals and aspirations of our own to guide us in helping our clients to deal with the matter.

Details of Specimen Baths.

I believe that in no way can we better get to close quarters with the subject than by examining the details of any specimen building designed under fairly advantageous conditions. For such an example last year I prepared a sort of model plan which has some relation to the baths now being erected at Plaistow. I prefer this year, with your permission, to make use of a plan which has been adopted for the Stratford baths, because it is, as a plan, somewhat in advance of the other. I almost feel that I should

apologise for taking one of my own buildings as an example; but it seems obvious to me (and I hope to you) that it is better to deal with a building one knows thoroughly than to speculate upon others (however superior) designed under conditions known to few but their authors and projectors.

The building comprises three swimming baths, respectively for first- and second-class men and women, and warm baths allotted to the two classes in the proportion laid down in the now obsolete Public Baths and Wash-houses Act of 1846; also a small Turkish bath. The site is at the corner of two streets, and a

right of way on the third side forms practically a third street. It is not an ideal site, but very fair, especially for London. The main entrances are from the Romford Road, a fine, wide thoroughfare, and there is a special entrance for the Turkish bath and emergency exits on the two other sides. The entrance hall is, as I think it always should be, the key to the plan; and it is so designed that it can (and I hope will) be used by all classes, both men and women, for I hold it an anachronism in these days to have separate entrances for the classes and sexes in a properly-planned building. It is not necessary in a railway station nor in a post-office. Why in public baths? I am convinced that it is a matter of pure prejudice. At any rate, I have not yet heard any really good reason for it—nothing stronger than the vague statement that the public "won't stand it." The two subsidiary entrances are provided for dividing the sexes if so desired, but more especially to allow the central entrance to be kept free when entertainments are held in the great bath hall. Had it been possible, I should have made this hall much larger. The entrances are dominated by the offices, and in the rear of the hall is a refreshment bar, the convenience and comfort of which will be fully appreciated by the bathers. Immediately in the rear is the first-class swimming bath hall, 125ft. long by 53ft. broad at the platform level, 150ft. by 65ft. at the gallery level. Still further in the rear are two baths, respectively for women and second-class men, and between the two the towel laundry, boiler house, &c. On the left hand side of the large bath hall are the men's warm baths, and on the right women's warm baths and the Turkish bath. The committee room and a residence for the superintendent are on the upper floors of the front building. There are one or two particular features in the plan to which I wish to draw your attention as illustrating certain principles.

The central entrance hall is, as I have said, the key to the plan, and the arrangement of

FACADE, PLEASINGTON PRIORY.

the corridors and entrances is such that the various parts of the building can be used separately without interference with the others, yet without loss of control by the offices.

The first-class bath is designed for use as a racing bath; and here I should like to acknowledge an error of judgment in replying to a criticism of my last paper by Mr. E. Harding Payne. Mr. Payne pleaded for more consideration for those who use these baths for racing and sports; and I think I expressed the view then that as baths were only so used occasionally, racing men's requirements should take a secondary place. Subsequent consideration of the matter in the light of the effects upon other physical and mental exercise of the sporting element in the English character convinces me that nothing will popularise the use of the swimming baths more than the encouragement of racing and aquatic sports generally.

The situation of these baths is just opposite one of the finest technical institutes in the country, and the corporation, seeing a good opportunity of encouraging the physical side of their students' education, have agreed that the first-class bath shall be made as attractive to them as possible. The length of the bath is 100ft. and the breadth 35ft., and the depth from 7ft. to 8ft. 6in. The yard being the unit of length in races, and the divisions mostly multiples or parts of 100, that length in feet is convenient; 150ft. might be better, but it must be borne in mind that the cost of water in most cities is such as to make the frequent filling of so large a bath very costly. And it is desirable that in hot weather at least the water should be changed every day.

When the hall is to be used for swimming entertainments, the dressing boxes round the sides would be folded back against the walls, allowing a width of 8ft. 6in. on each side and one end of the bath for spectators, leaving the other end for performers. The galleries will be constructed with tiers of seats at such an angle that all will have a very good view of the bath pond. In short length races it is frequently necessary for the swimmer to finish at the opposite end of the bath to that from which he starts, and unless this is done swimming he has to pick his way along the edge of the bath, to the possible discomfort of the first row of spectators and the danger of slipping to himself. Either of the corridors outside the bath hall will provide a free gangway for this purpose.

Swimming baths are generally closed during the six winter months. The expense of heating the water to a fair temperature and maintaining it is great, and in cold weather the general public do not show much inclination to bathe. It is usual to keep one of the smaller baths going in winter for the sake of the more vigorous minority who find a swim as beneficial in winter as in summer. During the winter months the baths will be boarded over, and the hall is then available for concerts or other public meetings. I must not speak at more length on this part of the subject, and will only draw your attention to the very necessary provision of plenty of exits from the platform and gallery levels. The two smaller baths are similar in construction, but have a small gallery at one end only. The second-class men's bath will be fitted up in winter as a gymnasium.

A complete system of subways connects all the baths, and, indeed, all points of the building, with the engine house and boiler room, and this I regard as a very necessary provision, obviating the burying of the very numerous water, steam, and other mains which form so extensive and important a part of bath construction. There is little else in the plan which calls for special description, and I fear that the compass of my paper will not permit me to enter into a description of the constructional features of these buildings.

The New St. Pancras Baths.

With regard to the new baths for the Vestry of St. Pancras, London, now in course of erection (Messrs. Aldwinckle and Sons are the architects), the site is an exceedingly awkward one, ill-shaped and limited; so limited, in fact, that it must have entailed very long and

very tedious efforts to have put so much upon it. I had a somewhat similar site myself to deal with at Marylebone, and know something of the difficulties, and, indeed, I am afraid that in London we seldom have it otherwise. Then the position and means of access to the first-class bath were designed with a special view to the very stringent regulations of the London County Council as to approaches and exits; because it is proposed to use the bath hall in winter for public entertainments.

The first-class bath will be a fine one in many respects, and not the least in an architectural sense. I draw particular attention to the lighting, which is uncommon though not entirely new in principle. The most usual form adopted is that of a large lantern and skylight, but it is found in practice that a skylight forms a very large sounding board, spoiling the acoustic properties of the hall and reflecting every sound to such an extent that it is almost impossible to hear oneself speak when the bath is fairly full of bathers, laughing, shouting, and splashing about as bathers will—especially boys.

Mr. Aldwinckle has, therefore, adopted a trefoil form of roof. The lower half of the centre vault is glazed between iron bars for the whole length of the hall. Opposite this and at an average distance of 4ft. is a skylight in the roof covering. The architects are confident that this will entirely obviate the nuisance and inconvenience of the ordinary lantern. A fine gallery is formed above the boxes built up in tiers, but I venture to think that the rise is not quite sufficient. I believe, however, that the County Council will not allow more. The dressing boxes are all wood framed. Three douche compartments are provided at the entrance-end of the hall, a provision to which I refer more particularly later on. The second-class bath is similar in size to the first-class bath, which is unusual. Although it is by no means universal, I think it will be found that in most cases the second-class bath is used mainly by boys, and it is, therefore, not necessary to have it so large or deep. In this bath a great number of the dressing boxes are placed in transeptal bays, which allow of a greater number than would otherwise be possible. An uncommon provision is that of boxes to accommodate respectively two and three boys. The partitions of these boxes are of oiled slate kept 6in. short of the floor, and the doors are of wood, and quite short. Four douche baths and a foot bath are provided in this case—and for obvious reasons.

As I shall not refer again (except casually) to this particular form of warm bath, I draw your attention to the ingeniously contrived position of the second-class warm baths, which are practically built out on cantilevers round three sides of the swimming bath hall.

Provincial Baths.

The Guildford Crescent Baths at Cardiff, designed by Mr. Harpur, the borough engineer, are another example of planning under difficulties, and I think you will agree with me that they have been well met. They are notable, too, for the warm lavatories and douche baths in connection with the dressing boxes. As to the reason which led the corporation to adopt this innovation and other progressive ideas in connection with warm baths, I cannot do better than refer you to Mr. Harpur's report to the Cardiff Council, dated June 9th, 1893, which was quoted *in extenso* by Mr. E. Foster in the paper he read upon this subject before the Incorporated Association of Municipal and County Engineers at the annual meeting in 1899. I shall describe these warm lavatories later on in connection with the washing baths. The small Turkish bath is by no means a frequent provision in public baths, but one which will be adopted more in the future.

The plan of Cheltenham Baths does not, I fear, in its arrangement do justice to the enterprise of Mr. Hall, the borough engineer, in his endeavour to bring it up to the level of modern requirements. It is a thankless task at all times to alter an old building. I draw your attention, however, to the really handsome waiting-room for first-class bathers. This is a boon in its way, for on certain days and at

certain hours one may have to wait one's turn for a bath for as much as half an hour. The rounded end to the swimming bath is a purely architectural feature and of no special use. The columns in the middle of the footway are out of place, but they were part of the old building.

The plans of Tunbridge Wells Baths, again, do scant justice to the building itself.

The plan and section of a Dutch bath which Mr. Nieuwerkerken, the architect, sent me a couple of years ago, is interesting as showing some striking variation from the English plan. I note, by the way, that the site is "quite English." The length of the bath is about 75ft. and the breadth 25ft. The depth is, however, 10ft. at the lower end, or 3ft. more than in the English bath, and the slope is graduated in lengths. There is ample width for the footway, which with us is nearly always narrow. The dressing boxes, too, are roomy.

The magnificent establishment at Harrogate does not include a swimming bath, nor indeed washing baths of the ordinary description, but I asked Mr. Baggallay, the architect, to lend me the drawings and photographs for exhibition as a standard of architecture which we may yet hope to see realised in public baths. There is little more I shall have to say upon the subject of swimming baths, because I should necessarily have to repeat so much of last year's paper; and I desire on this occasion to discuss the details of

Warm or Washing Baths,

which, happily enough, are engaging more attention at the present time than in past years. At a time when every house with an annual rent of £28 upwards is provided with a bath-room, it would seem unnecessary to provide public warm baths, but I am credibly informed that in most cases—that is, among the smaller houses—these bath-rooms serve as handy store cupboards, and when we bear in mind the kind of bath and water supply which can be afforded in a jerry-built house, and the want of constant attention necessary to keep the bath clean, we can scarcely wonder that it becomes in time uninviting and not to be compared in comfort with the well-constructed, scrupulously clean public bath, replete with every convenience. There will always be, too, a very large number of people living in model dwellings, and even of the better-class lodgings, to whom the luxury of a bath would be unknown were it not for these public baths, and for this very large class it behoves our public authorities in the interests of public health to provide the best facilities possible for a good wash at the smallest cost. We in England pride ourselves as a nation upon cleanliness; but I fear that truthful statistics showing the proportion of us which is accustomed to regular bathing would at least show that we are very far behind the unspeakable Turk, for instance, in this matter.

The problem before our authorities then is how to induce the masses to take kindly—indeed eagerly—to the delightful habit (when once learned) of keeping themselves clean; and this problem is being grappled with very energetically in our large cities, and Liverpool is, I think, well to the front in this matter. Much has been written, and much more will follow, upon this subject, and in due time much will be done—there is a large field for enterprise. I do not propose to weary you with a history of the development of the public warm bath, or to discuss the several forms which have been adopted in this and other countries. It is too large a matter to form part only of a paper. I prefer rather to ask you to study the arrangements of one or two good modern examples.

It appears to be generally recognised that if we are to make the washing baths popular with the working man they must be brought almost to his door, instead of being grouped in one or two large establishments in central positions. A working man may be induced to walk or ride a mile to enjoy a swim, but scarcely to get a bath. The scheme now in course of adoption in the larger cities, and notably in Liverpool and Cardiff, is one of decentralisation and the establishment of small sets of baths centrally placed in

comparatively small areas within easy reach of their patrons. Necessarily, if decentralisation be carried too far, the establishments become too small to be economical; but a small set of from twenty to thirty baths (if they become popular) should go far towards paying cost of administration. Of course, everything depends upon the initial outlay in construction, and the cost of maintenance and administration. These matters depend again very greatly upon our skill as architects in planning simply, and constructing cheaply and durably, and it is to such points I particularly invite your attention. Perhaps one of the simplest plans for such an establishment is that of one of the people's baths for the City of Yonkers, U.S.A. It consists of waiting lobbies respectively for men and women, a ticket office commanding both, six washing baths for women and fourteen for men. These proportions could be easily varied. The superintendent's room would no doubt be placed over the waiting halls, and the heating apparatus, coal stores, &c., underneath. No side lights are required in the walls, so that the amount of ground and frontage occupied is little more than is necessary for a workman's cottage. Where more ground is available, the plan designed by Mr. Court for the Corporation of Liverpool is very compact. There is apparently a little waste space on the women's side, but this merely provides room for the erection of four more baths at a future time.

It is so difficult to determine from time to time in what proportion the sexes will bathe that I venture to suggest that all these establishments should be so designed that the proportions can be varied by simple means. A little rearrangement of the passages will easily affect this. A small alteration in the approach to the laundry would effectually cut it off from direct communication with the ticket office, to the greater comfort of the superintendent. An even better arrangement would take the laundry out of the front building, placing it in the rear of the baths with a proper top light and ventilation.

Each bath comprises two compartments, one for undressing and dressing, and the other for washing. The dressing box should, of course, be fitted with a seat, hat and clothes pegs, mirror, and a boot jack—all fixed. (I am not describing Mr. Court's particular building.) The washing box is fitted with a sort of large foot bath, a seat, and a fine overhead shower or douche for cold, hot, or warm water. The bather first partly fills his foot bath with water, and washes and soaps himself all over, and then a gentle warm shower cleanses the whole of the body, a shower which can, at will, be lowered sufficiently in temperature to invigorate the body and close the pores of the skin. The amount of water used in this bath is very small compared to that required for the slipper bath; indeed, I believe six to ten gallons as against forty to fifty gallons.

Constructional Details.

Having planned a building as economically as possible, we have yet to construct it cheaply. With respect to the *carcase*, we are bound within limits of cheapness by building by-laws. Internal finishings can be as plain as possible, but nothing is gained by making them flimsy. Both wall and floor surfaces must be impervious and easy to clean and keep clean. For internal faces of walls I think nothing is really so cheap in the long run as plain tiles or glazed bricks, but these need not be carried higher than 6ft. For flooring, granolithic is certainly cheapest, but pressed tiles of terrazzo are not very costly.

In the construction of the bath compartment there are one or two apparent extravagancies desirable, which are, however, well worth the cost. It must be borne in mind that a large amount of dirt—and very offensive dirt—is taken into these compartments, and not all of it is washed off by the shower. Every horizontal surface forms a resting-place for particles of dust and dirt, every internal corner harbours them, every inaccessible nook forms a secure breeding place for objectionable and nameless life. The dirt may not be in evidence to the eye, perhaps scarcely to the sense of smell,

perhaps only in a certain closeness in the air. What we should aim at, therefore, is to so simplify the fittings as to render them easily and automatically cleaned all round, and to do away with internal corners as far as possible by rounding them to a fairly large radius. By keeping the partitions a few inches clear of the floor a number of these angles are avoided, and it becomes possible to clean the floor easily and effectively. The foot bath may be little more than a large glazed stoneware sink (which is cheap enough) and the top solid dish slate, but both should be bedded solid all round, no open joints or inaccessible recesses being left. The supply pipes are best kept above ground, the main pipes carried above the top of the partitions and the branches strongly fixed quite clear of the walls. The waste should discharge into an open channel common to each row of baths and formed with half-round white-glazed pipes.

The walls of the compartments can be variously constructed with wood, slate or glazed brick. Wood is, of course, the cheapest material as it is also the most open to objection. The advantages of glazed bricks are more apparent than real. The surface is too uneven, and the very numerous joints form small ledges for dirt which is not easily detected. Enamelled slate (while it lasts) gives a perfect surface, but it is easily scratched, and it is costly. Marmorite appears to be the most perfect wall lining possible, for it can be obtained in large slabs necessitating but few joints. At present it is too costly. On the whole, therefore (unless extreme cheapness is essential) I should prefer to fall back upon 6in. white-glazed tiles fixed with rubbed joints to any of the patent thin partitions now on the market. The surface is perfect and durable, it is not more expensive than glazed brick, and it is possible with the use of coloured or stencilled bands to give it a decorative value at very small extra cost.

The type of plan I have just described is suitable for the cheapest class of baths, for which bathers might be reasonably charged one penny. It is necessary to provide also a better class of washing baths which might be attached to the central swimming bath establishments, and for which a charge of fourpence to sixpence would not be unreasonable. I fear that it is with this class that we shall find most difficulty in getting rid of the old fashioned slipper baths. People who can afford to pay sixpence for a bath are inclined to resent any dictation in the matter of their established prejudices. Nevertheless I believe they can and will eventually be tempted out of their prejudices if our public authorities will exercise or allow us to exercise a little taste and imagination in the planning and fitting up of these establishments.

A great step has been taken in this direction at Cardiff—I mean in the provision of a plunge bath in connection with the spray baths. The idea is that after a warm bath the bather has an opportunity of invigorating his frame and combining with it a little amusement by a dive and short swim. There is one objection to this particular plan which I think Mr. Foster referred to in his paper last year.

People in this country at least have an unconquerable objection to bathe or to see others bathe in a state of what Trilby called "the altogether," and it would seem tiresome to have to don a bathing costume just for a few minutes in a plunge bath. I suggest as an improvement that the position of the warm bath compartments should be reversed and placed round the plunge bath close to the edge, with the corridor next the outer walls. A bather could then dive out of his compartment direct into the water, and in returning to his compartment dripping all over he would not have to pass by that part holding his dry clothes. There is another suggestion I should like to see taken into serious consideration. Is it not possible to make a few more steps towards Roman ideals in the matter of public baths? I know, of course, that we cannot expect a revival of the baths of Caracalla until the twentieth century at the earliest; but would it not be possible to take a few steps in that direction—say, for instance, an establishment where, for the sum of sixpence, you

might enjoy at will a modified form of Turkish bath, a swim, and a few gymnastic exercises with the opportunity of an adjournment afterwards to the lounge for a cup of coffee, the daily papers, and the latest war telegrams?

Lest you should doubt my seriousness, I will not go further, but it would be easy to pile up delights which would make the bath-house a most popular resort, and I venture to prophecy a most paying concern.

Mr. Harpur, superintendent engineer at Cardiff, has arranged warm lavatories in connection with swimming baths—one being provided to each two dressing boxes. The idea is that every bather before entering the swimming bath should have the opportunity of first washing himself all over—this is the rule in most countries. I must confess that I have some doubts as to whether this arrangement is reasonably economical, and I venture to think that he himself has adopted it mainly to meet some of the bathers' many prejudices. The plan of these lavatories and the arrangement of the fittings appear to me excellent; but I would rather recommend a simpler and more solid construction. I think a pipe enclosed in a pipe in the wrong place, and that all odd corners and spaces which cannot be easily exposed and cleaned are to be avoided at any cost.

You will notice that these douche baths have been adopted at Cheltenham, and I may add that I may shortly make an effort to introduce them in East London for the benefit of dock labourers.

Wash-houses.

The title of this paper is "Public Baths and Wash-houses," but I think the last word fell into its accustomed place without notice, because it has always been bracketted with public baths. But it does not really form part of the same subject, and I feel almost disposed to drop it with these few words of explanation. Public wash-houses have been established to enable the working classes to do their washing under conditions which are not attainable in the miserably small houses—rooms even—in which they often live, or exist. For the modest sum of 1½d. to 2d. per hour a woman can have the sole use of a compartment containing one or more tubs, unlimited hot and cold water and steam. Her washing will be wrung out for her by powerful hydros, after which she can dry it quickly in a steam-heated chamber. A large ironing room is provided, fitted with broad tables, ironing stoves and irons, and power-driven mangles. A creche is attached to modern wash-houses, where she can leave her small children in charge of a capable nurse.

There is not much variation in the plan of these wash-houses, and I think you may take those of Marylebone and St. Pancras as typical examples. The plan consists of a number of rows of washing compartments enclosed with iron partitions, and each about 3ft. 6in. square on plan. The main difference between the St. Pancras and St. Marylebone wash-houses is that in the former these partitions will be (as is more usual) high enough to screen off the washer from her neighbour's sight. At Marylebone the partitions were designedly kept low, but which of the two systems has the greater number of advantages I cannot say as yet. Opposite the rows of washing compartments are a few power-driven wringers or hydro-extractors as they are grandiloquently called. At Marylebone these are under the charge of a special attendant, as they are driven at a very high speed. Behind these is a row of drying horses, one corresponding to each washing box, and these should be so placed that each horse can be seen by the occupant of the particular washing box to which it corresponds. The washer is then able to keep a watchful eye upon the drying horse to prevent theft by others. In some cases I believe the drying horse is attached to the washing compartment, but it is obvious that this can be done only at the expense of great space.

Royal Society of Painters in Water-colours.—At a recent meeting of this Society there were seventy candidates for the vacant Associateships. One only was elected.

"BUILDERS' JOURNAL" SHILLING FUND.

OUR offer of a copy of the current issue of "Specification," the invaluable reference book for all connected with the building trades, sold at 5s. nett, is still open to anyone who collects twenty shillings for our fund.

The following subscriptions have been received since the publication of our last list:—

The British Fire Prevention Committee has decided to put its Reading-room at No. 1, Waterloo-place, at the disposal of the Building Trades' Gift for a further term, so that all communications should, as before, go to the original address of the Gift. The Fire Prevention Committee was guided in giving these facilities by the fact that the primary movers in the scheme are practically all members of that body. Mr. T. F. Rider, honorary secretary of the Gift, calls particular attention to the great liberality of the asphalt trade, practically every firm working in London having applied to assist, either on the roofs, paths, damp course, or the like, and the work hence being offered many times over. The work will be distributed among the six donors who applied first, the other firms mostly changing their offers in kind to cash donations. Mr. Rider further announces that among the materials particularly required to complete the scheme are timber joinery, red facing bricks, cement, lime, and some iron roof trusses. Scarcely any timber has been presented.

Views and Reviews.

OUR ANCIENT CHURCHES.

The Romance of our Ancient Churches! What a name to conjure with! What a theme for poet or historian! How unique is the position in our national life held by these buildings! What a strange glamour surrounds them; how subtle and delicate a perfume of long-forgotten days, how faint and tremulous an echo of harmonies long played out!

"The Romance of our Ancient Churches," as a title appeals to the imagination. We expect much, we anticipate something very good, but in this case we do not find it. As a title to this book it is misleading—it leads to disappointment. Perhaps it is only natural that, not finding here what we were led to expect, we experience some difficulty in doing justice to this book. But, indeed, it does not appeal to us.

There is a large amount of material collected together—facts about churches and their surroundings; that this one has an isolated tower, that one a chained bible, and the other a rood loft; but there is little skill displayed in arranging it. The book strikes us as the disjointed, chatty, amiable production of an amateur—amateur as architect, as antiquarian, or as writer. It gives us the usual antiquarian information, mentions some of the still undecided problems, and tells us about all sorts of quaint things, frid-stools, dog whippers and dog tongs, aumbreys and acoustic vases, bone houses, and a Dutchman who "attracted notoriety on the weathercock." Occasionally we find an interlude of "fine" writing, pervaded with an atmosphere of gentle sentimentalism; but of romance—!

The book is illustrated by nearly 200 sketches and drawings which, we must say, hardly ever do justice to the subject matter. With the exception of the frontispiece, it would be difficult to pick out a single one that is more than just passable. The printing and paper are good, and the binding satisfactory.

There is no doubt that considerable time and labour must have been spent in collecting the information here given; we only wish the result had been better. We cannot say we think that this book will prove of service to the serious student. It would probably be more

acceptable as a birthday present for a country parson's daughter. There are some good things to be found in it, here and there, but the best—or the worst—is the title.

"The Romance of our Ancient Churches." By S. Wilson. Illustrated by Alexander Ansted. London: Archibald Constable and Co.

THE DUPLICATION OF DRAWINGS.

This little handbook is intended for the experimental amateur photographer and for engineers, architects and others who constantly need reproductions of their drawings and tracings. The theoretical element has been reduced to a minimum, and the book deals almost exclusively with a clear exposition of the various ferric and heliographic processes, the four chief of which are: Ferro-prussiate (white lines on a blue ground), Pellet (blue lines on a white ground), ferro-gallic (black lines on a white ground), and brown (white lines on a brown ground). The ferro-prussiate is one of the oldest printing processes (being used by Herschel in 1840) and has the merits of simplicity and cheapness, but objection has been taken by some draughtsmen to its blue ground. The Pellet paper (variously known as "Cyanofor," "Positive Ferrottype," "Cyanographic," etc.) is certainly the most rapid paper, though it needs more skilful handling and four baths in its production. Ferro-gallic paper is not so rapid as the Pellet variety, but is simpler in treatment, and its black line on a white ground makes it very popular with many; but, unlike the Pellet paper, this white ground is rarely pure. The brown or sepia process gains in favour on account of its adaptability for producing a number of positive copies from a negative intermediate (white line on brown ground), printed directly from the tracing. Kallitype, Obernetter, Uranotype, and other processes are dealt with, and an interesting account is given in Chapter IV. of Mr. Brewerton's method of utilising in tri-colour work the pure blue colour of the ferro-prussiate process. The Kallitype and Obernetter processes give dark, rich tones very easily, and, Mr. Brown remarks very wisely, "it is a mistaken policy to torture the blue ferro-prussiate image with chemical reagents, with the object of imitating these other processes." Mr. Oscar Bolle has suggested that, as the colour of blue prints is similar to that of the old Delft pictures, they may be used to make imitation tiles by mounting them on glass or wood and then coating them with size and varnish. The book explains the various apparatus used in the several processes enumerated, and can be recommended as a short practical treatise on the subject. It is fairly well illustrated, and includes some real examples of ferro-prussiate, ferro-gallic, and brown papers.

"Ferric and Heliographic Processes." By George E. Brown, F.I.C. London: Dawbarn and Ward, Ltd., 6, Farringdon Avenue. Price 2s. net.

Architectural Association of Ireland.—

On Wednesday last between twenty and thirty members of this association paid a visit to the Dolphins Barn Brickworks. The party was received by the directors, Messrs. Fox, Allen, Ward, and Doyle, who, with Mr. John Good, the managing director, and Mr. Milligan, works manager, personally conducted the members over the extensive works, and explained the latest methods of making bricks by machinery.

Ordnance Survey.—In the course of a paper on "Twelve Years' Work of the Ordnance Survey, from 1887 to 1899," read before the Royal Geographical Society, Sir John Farquharson said with regard to complaints of the slow production by the Ordnance Survey of its topographical maps, as compared with the rapid production by other countries, that the systems employed in this country and abroad were so different as to afford no ground for such comparisons. Foreign countries did not publish at all such maps as our 10ft. plans, or even those on the 25in. and 6in. scales, but only topographical maps analogous to our lin. maps.

ARCHITECTURAL ASSOCIATION.

THE DECORATION OF CHURCHES.

By H. C. CORLETTE.

A SPECIAL GENERAL MEETING of the Architectural Association took place last Friday evening, preliminary to the ordinary meeting, to receive several changes in the by-laws proposed by the committee. Mr. G. H. Fellowes Prynn, the president, was in the chair and put the proposals, which were carried unanimously. These are as follows:

To add the word "*Honorary*" before "*Secretaries*" in by-laws 17, 21, 25, 30, 32 (in two places), 43, 48, and 51; these alterations being necessary, as Mr. Driver has been appointed secretary by the committee instead of assistant secretary. By-law 38 to read "*half-a-crown*" instead of "*one shilling*." At the end of By-law 16 add: "Any ordinary member elected between January 1st and April 30th in any session shall pay a sum of half a guinea in lieu of one guinea as the subscription for the remainder of the then current session, in addition to the entrance fee of two guineas."

The ordinary general meeting was then held. The minutes of the last meeting having been read and confirmed, Messrs. G. Drysdale and O. R. Goodman were elected members of the Association. It was announced that Mr. H. C. Corlette had been reinstated a member. Mr. G. B. Carvill, hon. secretary, then announced the donation of twenty-seven models and casts of foliage, etc., made for work executed by the late William Burges, A.R.A., by Mr. John S. Chapple. On the motion of Mr. R. S. Balfour a vote of thanks was accorded to Messrs. Farmer and Brindley for allowing members to visit their premises on March 10th. Mr. H. C. Corlette then read his paper on "The Decoration of Churches," of which the following is a summary:

New ideas concerning decoration are most likely to be derived from the study of applications of ideas whose use and value has been proved by experiment. It is no more than to do in matters concerning design just as you do when you go for a walk—you lift your foot and take a step upon the encouragement derived from experience in locomotion; then you take another, but a different one, and so proceed. To do no more than read or hear about decoration, and not venture to try and do some yourselves, is absurd.

When I accepted the invitation to read a paper upon this subject I had little idea what this involved. A very little reflection was required to assure me that to deal with decoration under ordinary circumstances need present but few real difficulties; for it seemed merely to call for some statement of my own opinions and preferences. But to speak about the decoration of churches was to tread at once upon very debatable ground, invite hostility, pleasant enough in itself but productive of little if it contended merely for propositions involving religious conviction or taste which necessarily admit of little solution by argument. So it was advisable to find other grounds than taste alone and to make them the base from which to urge the desirability, in fact the need, of decoration in our churches. But as artists we are not very much of one mind concerning the principles involved in design and, unfortunately, as churchmen, under the present condition of things, our opinions largely differ upon points of detail, though I hope not so much where essentials are the question. But desiring to be courteous to your several points of view I decided to avoid, as far as possible, any questions which are better not discussed on occasions of this kind. So when it became apparent that there were distinctly two broad aspects from which to view the subject—aspects which cannot be separated—it was inevitable that the course of the paper should be devoted largely to a series of suggestions of principle which should attempt, first, to show the intimate, the necessary relation of these two sides. Then, as far as possible, the natural course to pursue was to deal with each of these two leading ideas in continuation, and briefly take notice of a

variety of matters in more detail. Let me now ask you to come with me to meet these general considerations.

What are the larger ideas we should adopt in determining the relation that we must maintain between one part of the decoration in a church and another? This idea resolves itself at once into two general aspects—the ecclesiastical and the architectural.

The first deals at once with the object of the decoration and with the subject it may represent. And these both may be satisfied by the choice of theme if figure work is possible, and the selection of appropriate symbols, whether they be chosen among those taken from animate or inanimate nature, or from the colours which themselves may speak much thought to those who have been taught to read what they may reveal.

Next, architecturally, we are led to think of the manner by which that object may best be realised and the subject be given appropriate expression in the field available. Our bare materials have been led on from their incorporate state after having been severed from their condition in nature to other realms of usefulness in our service by the exercise of man's skill. This skill has given them place in a building which is the result of thought, of design. The element of art has been introduced by that power of design, and to the capacities of will and mind are now to be added some expression of those of the imagination and affection. Without these, from mere technical ability, we cannot derive architecture, that union of the arts which so pre-eminently appeals to us through the avenues of our emotional and imaginative faculties. And it is in decoration by means of colour united with form that we add those beauties which are the complementaries to all the preceding ingenuity. Without decoration in some form we cannot be satisfied; it is the sign of life, of fruition, of satisfaction, everywhere in nature. After every wintry death there is always a revival of fuller beauties in the spring for which we look with anticipating hope and joy; but sombre gloom is derisive; it weighs heavily like a fog over the spirit of happiness for which we always crave and seek as a perpetual companion. Therefore give men decoration which is not dull, and you may help them to be fresh too, and bright, and full of sympathy by the example of those associations in the midst of which they find themselves continually.

We have been thinking of general considerations. And to these there must be some focus for all our ideas—some central point of interest, both ecclesiastically and architecturally, which shall be the ruling idea to which all others in the whole treatment shall be related. And it is only by keeping this principal idea constantly before us that we can effect a prevalent unity in the completed scheme. Is it necessary to state in what position this central thought shall be? Where is the most important part of the church ecclesiastically? Where is it architecturally? Is it not to be found in that portion of the choir which is known as the Sanctuary, the Sacramentary? The position of the altar, or call it Holy Table if you will, surely this indicates the place where all the ideas, the thoughts, the aims, the aspirations, the complete attention of both clergy and congregation should be concentrated! It is there that the most sacred part of Christian ceremonial is enacted. And it is within the immediate precincts of this spot that all the glory of art should be used to aid us in appreciating the sincerity, the sanctity and the beauty of ideal which is there principally represented. If you would require precedent for such a method have you far to seek? Go back to the beginning and see in the type of what the arrangement of a church should be, how the same order was observed. In the Jewish Tabernacle you have it all.

The three divisions of the Tabernacle were a presentment of many things. But for our present purpose they showed what was to be the general ecclesiastical arrangement of a Christian church. And in it we have known, from the earliest times, those separate but related parts, the nave, the choir or presby-

tery, and the sanctuary. It is necessary that our attention shall be confined to the principles of ecclesiastical decoration we may derive from this source, and these chiefly appear in the fact that the decorative treatment was carried from the Outer Court to the Holy and Most Holy Places as a progressive development moving upwards to a more perfect expression in strict relation to the same increase in the solemnity of the ceremonial.

By colour alone we may have thoughts suggested to us. In hues of gold we see typified the security and undeniable truth of ruling principles; in blue the lights brought down to earth by the prophetic capacities of a searching imagination exercised under due subjection; in the red of blood the food of life, the power of human reason in full and sympathetic exercise; and in the whiteness of purged silver the purity of unselfish affection. And you will find that these colours and these metals with brass, or copper as it probably was, are the colours so often specifically mentioned in the descriptions of the Mosaic Tabernacle. They all had their office, their set place, position and meaning.

The architectural design of a church is not a matter only of the inception and execution of aesthetic dreams. Architectural history necessarily covers a consideration of the causes of certain ideas as well as their execution as problems in structure, that is as works of building. In this aspect we are brought into immediate contact with what we may well consider the marvellous engineering skill of the mediævals; and this skill stood not alone in cold and unsympathetic isolation. It was not exercised, divorced from considerations of beauty; for the mechanical elements of design were inseparably wedded to the architectural, and the product of the union was seen in the issue. There were the two parents of one being always discernible in the composite whole. The power of the two found expression far more effective in combination. The one resulting work of art, or rather nature, for its production was an act of nature, was as a voicing of the powerful spontaneity of utterance which that language expressed by the beauty of silent form and colour. It was man's privilege to speak so in days when simplicity and sincerity of aim were more to him than self-grafted, forced and self-conscious art. The one work was architecture, the corporate expression of art as a unity. And the elements to be discovered in the composition of this effort towards a unanimity of expression are to be seen in each branch of human skill, of whatever kind, that was called in to offer its tribute to this aim. There was the practical, the structural, the scientific, the engineering side by which some forms of skill were expressed. They were the display of sound common-sense based upon careful observation of natural static laws, the qualities and properties of materials and the allotment of each in consequence to its proper place and function in the scheme. They were the expression primarily of man's will under the guidance of his reasoning, thinking, observing mind. But reason and will alone do not produce architecture, that is art, in its highest sense. They give us building and engineering purely, simply. The entire resources of man's being must be called in to aid if we are to see the manifestation of work which shall always appeal to the sympathies of other men. There must, therefore, besides the expression of his will and reason, also be afforded some scope for his imagination and his affections. We have as architects to grasp and act upon the knowledge that it is necessary before all things in art, to use our mind rather than our memory, our own observations, and not so much the catalogue in printed type or illustrated page with which the libraries are overflowing. Avoid the fret and waste of incessant labour among books and learn to be idle in order to think and dream. Go to the works in the library of nature. Creep about the mysterious piled walls of poetry and prose in stone and brick. Let us learn to design by the study of design not by the unweaving of theories of supposed laws derived from original interpretations of natural suggestions.

Let me now touch upon another aspect. It

is necessary that in decorating a church we should subject our scheme to some one ruling principle—one which shall enable us to keep always constantly in view the effect we may desire to produce. And by effect I do not mean merely an effect from the æsthetic point of view, but, without disregarding this, from that of a creative impression. By a creative impression we should understand that one result the whole produces upon the responsive spectator. You know well enough how externals affect the mind and whole being of anyone who finds himself confronted by them; and it is almost trite to say that we are expected by each opportunity to express by means of architecture those feelings which are most required by the end for which the work has been begun. And so, is it not necessary that we try first to make men feel by their surroundings that they are before a presence which should at once call forth a reverent attitude of mind? Let us, then, have a breath of reverence first amid all the beauties you may devise. With such an end in view, it will be necessary to avoid the theatrical, the striking, the bizarre element in all decoration that may be used.

It is not easy to arrange the various ways in which this subject may be approached architecturally—at least, not if you try to attack it by any orderly method. Under the first division of the subject I separated it into two leading aspects; and under the second of those—the architectural—there seem naturally to fall three sub-sections. Under the first of these we had better, perhaps, consider the treatment of simple structure decoratively; that is, by the use of such colour as may well be introduced in the necessary parts of the building. In the next, the application to that structure of a simple and partial scheme of decoration, adopting largely only conventional pattern design, or diaper, and such like ways of introducing what is required, and under this heading might also be included the use of colour, sparingly, in the windows, on the floors, the roofs, and in the furniture. Then we might permit ourselves to be more lavish and think of a complete scheme for a fully decorated church; but the two latter will probably lend themselves better to our purpose if they are not treated quite apart, but as merging the one into the other.

But how shall we decorate our churches? With what means, what materials, shall we set to work? The list of methods is almost without end. It may be of some use to survey the catalogues and venture any remark or suggestion that shall occur, and for convenience I shall give you heads and sub-divisions so that we may, to a certain extent, be methodical. Broadly we have to consider surfaces horizontal, vertical, on the slope and on the curve, such as for instance: 1. *Flooring*, and the things about the same level to be used as the furniture of a floor. 2. *Walls*, flat, or with arcades and windows, in light and shade. 3. *Roofs*, including wood, or stone vaults, domes, open timber work. 4. *Light*, natural and artificial. 5. *Furniture*, such as the font, seats, pulpit, organ, screens, altar, reredos, &c. 6. Specially decorated parts of the structure.

Let us take the floors first. The unredeemable hideousness of the present day encaustic tile with its bilious yellow art shade, its pinks and blues that stare with such effrontery—these are, as a rule, too terrible to think of. There is surely no reason why glazed tiles for a floor surface need be so grossly vulgar as they often are! But they are cheap; they may easily be procured; they satisfy the untrained taste of those who demand showy brilliance and cheap tawdriness in place of quiet ease of colour, and repose. They leap at you when they should lie prone upon the floor of which they should be a part, not a mere ruse to attract our eyes to the region of our boots. Above all things in treating a pavement let us endeavour to keep it where it is. Let it lie. Do not make it restless. Not too startling, like a thing ready to meet your gaze half-way. It may be very beautiful, but, at the same time, if coloured the colours should not wrestle with each other; they may be many, but in effect they should be one.

The flooring may be of wood. But as we

are thinking of the decoration that it is possible for us to get by a thoughtful method of dealing with it, it is not necessary to dwell at length upon the ordinary boarded floor, except to remark that if the woods were more easily available it would be possible to discover many a fine and quiet beauty in the various textures, the grain and the colour of several varieties of wood used simply as well set boards; they might be polished or not. Wood, too, is better in northern latitudes for this purpose, because it is not so cold as any form of flagging, or tiling; but in England we do not see the floors of our churches as they do across the Channel, for we are wedded to the formal, long, depressing line of fixed benches, or to ranks of deep chairs hustled together and screwed up to keep them quiet and in place. Perhaps in some respects it is well so, for order is truly better than noisy muddle, though the long, horizontal lines of bench certainly do not, usually, help the architectural treatment as a whole. Chairs are better, for they are more in sympathy with the prevailing lines of Gothic art. Let us accept, then, the fact that for the present the greater part of every nave floor is to be permanently hidden from view except we wait and study it in the dips between the edgy waves of wooden seats. Then what have we left us which may, without futility, be dealt with by design? There is the space about the west end. Large it should be; then there would be scope for your energy, and room for our feet, and we should not feel that commercial considerations had overruled those of decent order and dignity. There would be space for the font to stand free and unencumbered, so that it might speak what it may well say both by its use and the beauty of design in which it may have been conceived. It would not then be hustled into a corner, which it is made to seek as a resort, as if it were a thing of comparative insignificance. Give it place, and give it dignity. Let us show that by our treatment of it we know its use, and respect the purpose for which it is required.

There may be a porch or porches. And it seems reasonable to suggest, if these are to be paved with thoughts, that those thoughts should be related as introductions to those that shall be found within the inner doors.

We are still dealing with the first idea—the use of simple materials, and for a floor there are many such that are always available. The use of boards or wood blocks for the body of the church which is covered by the seating seems to be the suggestion offered by common-sense for a reason already stated, but in the aisles or passages, and for the choir and sanctuary floor something more interesting is required. It is not necessary to discuss tiles further, and the many patent flooring materials may speak for themselves to those who have experimented with them. Some are inoffensive enough, but many are rather trying in their dullness, so far as colour is concerned and lack interest otherwise. Plain stone flags, or a broad use of two or at most three different colours in any materials—either of these ideas can produce happy results; but there seems to be a common fault among us by which we too much incline to cut up the floor surface into little patches. We use too small a pattern, or without any pattern we divide the pieces into diminutive parts, which increase so largely the cost with no compensating effect. Quite the reverse. We derive this peculiar tendency no doubt from the influence which modern tiles have exerted upon us; it would be preferable to see the mistake made in the other direction where the floor is concerned, it would help us to be rid of the analytical, the too logical and mental view of things, and urge us to quit the habits of a fly and adopt by preference those of the eagle; we should be freer, more imaginative, more comprehensive, in looking at things then. It does not do in architecture, or in any work connected with it, to dwell too much on detail before a general idea has been conceived, so that some attempt may be made to work up to it. By following this method details would be kept in place and always

subject to the effectual combination of the several parts.

Any pavements in the body of the church are undoubtedly best kept in relation as a unity. There should be some kinship both in colour and design. They should not be dealt with in the different parts like separate families; each opposed in aim and idea to the other, and all the children pieces composing them quarrelling among themselves. Those, too, in the choir should bear some link in their design which binds them in their relations on two sides. First to the nave, and next to the sanctuary. It is consistent, too, with the principle evident in the design of the Jewish Tabernacle that we should increase the value, the beauty, the significance, and the rarity of our work as we approach the most important part of the whole undertaking; for the sanctuary should be architecturally, as it is liturgically, the most important centre of all our ideas. Therefore it follows that we may endeavour to express more thought by our work at this point, and, as a consequence, the work in the sanctuary should, in the same respect, differ from that in the choir.

Before quitting the subject of floors, it is natural that some reference should be made to the use of carpets or rugs, or both, in the sanctuary. These may be very beautiful accessories, but they may be—they often are—hideous excrescences when, as is so often the case, they are ill chosen, both for their pattern and colour.

If we are limited to the introduction of only so much decoration as can be obtained by the materials of the structure, and the means usually adopted for their preservation, such as painting or oiling the woodwork, we already are possessed of an ample opportunity. Say we were to use brick! Need all the bricks be the same colour? Need they be merely laid side by side, bed on bed, with no more thought than is required to set them truly in bond? Surely not! If you have decided to use brick for your walls, it is of course possible to use it throughout for the piers, arches, and windows, but may we not provide a welcome contrast by showing the brick in the mass, and plastering some of the detailed portions of the composition; or the idea might be reversed and the mass plastered, leaving the details to show the essential materials. And this use of plaster as a really beautiful material should commend itself more to our minds, if it has not already a very high place in them. Then again, are we limited to brick, or to brick in conjunction with plaster? Certainly not. Externally we may use any combination of materials which are able to make themselves offensive to the assaults of climate. But it is not my intention to deal particularly with the decoration of churches so much from this point of view, the internal treatment is quite sufficient for one paper, but naturally the exterior lends itself to other methods and is subject to the control of different principles from those which rule the consideration of interiors.

It is quite unnecessary to do more than remark that the use of stone allows us to adopt every variety of treatment for internal decoration. There is naturally a much larger choice in the selection of materials, for we are at liberty to use the softer as well as the harder stones without fear, and this provides an almost unlimited palette of structural colours. How and by what means they may be combined must be left to individual taste, but in using them we should never forget the value of texture, the quality and nature of the tooling adopted in finishing the surfaces, for it is upon this detail that the beauty of stonework so largely depends. A rough surface in the masses with a fine finish on details makes a great difference in the ultimate effect, even if only one stone of one colour is used throughout. Different stones of similar colour, or rather other shades of the same colour, produce wonderful results, and it is gratuitous to speak of combinations of dissimilar colours, for it is an obvious method by which we may gain what is required. Brick with stone dressings; stone with brick dressings; stone surfaces with plaster details, either white or coloured—preferably with the ground

chippings from the dressed stone—or plaster surfaces and stone dressings; these are all familiar ideas.

The roof or ceiling of a church, however simple the structure, may well be used as a means of obtaining much decorative effect. We are able to do this by various ways; the mere arrangement of necessary timber will do a great deal if it is done with thought, not merely by following the customary dulnesses of a puerile text book on what is called construction. If you do not show your wooden roof structure as a part of the design, but cover it up with a stone or brick vault, a plastered ceiling of brick, concrete, or wood, or a boarded one, much can be done with these. A stone vault with its moulded ribs should be beautiful in itself, even though the stone used be of the usual pale shades of cream or yellow. But need the ribs be the same colour, or even the same stone as the filling? And may we not sometimes use stronger, more positively coloured stones, for a vaulted roof? If the ribs are of a different stone, or a different colour, from the filling, at least the colour of them should merge into the ground of which they are the structural support, so that they do not unduly stand forward from it as assertive streaks. The same ideas apply to the use of bricks as stone, when we think of them from the decorator's point of view. A plastered inner ceiling, whatever be the support that carries it, may be dealt with in many ways, but it is sometimes a difficult material to deal with except we are satisfied with whitewash, which is truly most valuable. The great need, though, in using plaster, if we wish to finish the surface in a colour, over the whole area, is to find some satisfactory tempera medium. By satisfactory, I mean one that will not readily perish on new plaster. Or else we must perhaps seek the remedy in better plaster. If we succeeded in finding this it would be possible, without misgivings, to do some excellent, but simple colour work by finishing in blues, reds and yellows—or, rather, golds—instead of being so much restricted to the adoption of the safer white and cream washes. It would be an easy matter to paint the plaster, but tempera seems the more natural medium to use in colouring it, and it is less expensive in first cost, as well as for the labour and skill required to put it on.

With a boarded ceiling there is a wide field open to us; we can paint or distemper it at will with little fear of the results if the boards are, as they must be, thoroughly dry. I am inclined to think that we should largely discard the use of oil paint when we may, except as a preservative, where decoration is concerned; especially in cities, where oxidation rapidly alters its colours. I am referring more particularly to cases such as those we are at present considering, that is, where the only decoration we may introduce must be a part of the necessary finish to some simple work. One reason for my saying that we should avoid the too frequent use of oil paint as a finish is because tempera, if properly used in a safe position, is more permanent. It retains the original brilliance of its hues longer, and they possess a more beautiful and transparent quality, like the freshness of water-colours almost, when used as a ground to cover large surfaces; but for highly decorative work, and pictorial work which is part of some decorative scheme, let us use every medium, every means by which we may with most security and success obtain the end at which we aim.

The roof, the vault, or the ceiling of a church—call it what you will—affords one of the best opportunities for simple decoration in colour that we can find. There is no need to make it always white. There is never any excuse for permitting it to be varnished, though it may with advantage be stained if of wood. The beauty of gold, that is certain tones of yellow and orange, as a colour to be used as an open field of colour, all of us realise who have seen it in mosaic work. Blue, too, and red, the excellence of these we know as well, and the plain undecorated ground is often, perhaps, more satisfactory than one which shows more evidence of design in conventional forms applied to it. Reserve in the use of colour and design is often a means of

discovering better results than can be obtained by allowing ourselves a looser rein to fancy; it gives us breadth, simplicity, and dignity, as well as that much needed quality— repose. And if we can be sure of these in our efforts we have already secured that which is most to be desired. Restless, fretting, disturbing combinations should most certainly be avoided. Abjure everything in schemes for decoration, which is more an endeavour to show your own cleverness than to make the thing beautiful for its own sake. The best works of the past were surely produced more by unconscious than conscious efforts to do fine things. They were the spontaneous products of a natural capacity.

I have spoken about the walls of a church, but not of the windows in them. These seem naturally to suggest a few thoughts apart, for they introduce the important matter of light. And in this regard we have to think of two ways by which this essential property must be provided. By this I refer to natural and to artificial methods. With little internal decoration we can dispense with clear glass in windows to a large extent, and make the glass itself by its colour and design serve as an important feature in the decorative scheme, but if there is much colour and design on the walls and roof inside a church we require plenty of light by which to see it. This principle the Byzantines frankly recognised. Again, in southern latitudes, where the light is brilliant and strong, a little of it is sufficient for practical purposes, and it is therefore possible, in fact desirable, to use very deep hues of rich colour in windows where stained glass has been adopted. In northern climates, on the other hand, we cannot so well spare light, especially in smoky cities, so the tones of colour and the proportion of white to stained glass have to be studied carefully, always bearing this idea in mind.

Other factors in decoration are the position of windows, their height from the floor, their size, and their relation to the decoration, or decorated objects, within the building. The thought of prospect does not so very much matter, as the chief reason for the use of a window in a church is to admit so much light as is necessary under various circumstances. But aspect does matter a great deal, and especially is this so in hot climates; in these a large east window, unless it be a studded field of very deep toned gems of colour, is most unpractical. Suppose yourselves in the body of a church and looking eastwards. Over the altar and reredos there is a large, or even a small, window, designed strictly in accordance with the traditions of northern art; it is filled with clear glass, or, with the most hideous of all things, cathedral tinted glass; or with stained glass thin and weak in colour. If you can see the Sanctuary properly under such circumstances, and sit quietly without a positive feeling of irritation, you will be possessors of remarkable eyes. The most sensible, the most truly artistic thing to do would surely be to provide the actual light required by the use of side windows in the chancel, and to treat the east window, if any, as an integral part of the reredos, and to keep it in the same scale of colour tones if possible. This may not be an easy task where you are obliged to make translucent colours combine, in unity of composition, with others necessarily opaque. Obviously, too, in localities where plenty of light is always available the windows generally may well be smaller than where nature is not so prodigal. The height from the floor at which they will best serve their purpose is a somewhat troublesome question; each individual building calls for its own solution of the problem. The character, the type of architecture imposed by conditions, largely decides such a point, for in a small country church they would not be placed so high up in the walls as in a building designed for a town, since the building should always reflect the character of its surroundings within certain limits that I need not mention; the windows in a town church approach the sky in search of the light which cannot be so well secured at lower levels. Consequently we are led to consider our decorative attempts subject to these altering conditions. Shallow saucer domes like those,

say, at St. Mark's, Venice, are best lighted at their springing level, but deep egg domes are most effectively illuminated from the top after the manner of the Pantheon at Rome. The whole value of the dome of St. Paul's Cathedral as a decorative opportunity is lost, internally, because of its lack of an efficient eye, and where domes cannot receive a direct light by either of these methods they are likely to prove unhappy expedients so far as their decoration is concerned, though the difficulty may largely be overcome by allowing the windows near them to be filled with white or silver-toned glass.

It is necessary to attempt a few suggestions concerning the introduction of artificial light, and by artificial light I allude to that which is required to enable a congregation to see clearly. In dealing with artificial light several important things must be considered. The positions in which it shall be placed; the nature of the light available; its power; its colour; its height above the heads of the assembled people—these are the principal matters with which we should have to deal. And let us be careful to remember that artificial light may make or mar any decoration that is to be seen by its aid. If the fittings are bad you present a permanent defect to the building seen by daylight, so it is well that they should be carefully designed. There is a little room for improvement upon the vulgar common-place stock patterns always available, but the truth is that all these fittings, as well as other furniture, should be expressly designed and made for the building in which they are to serve. The lights should never be hung in a string down the centre of the nave; it ruins the architectural effect, it entirely destroys the dignity of the sanctuary, it blots out the altar and reredos, and it is not, practically, the most desirable position. For, further than those objections already stated, this method is not the most satisfactory way of equally distributing the rays. If there is an arcade, the happiest position for brackets is on the east side of each pier. This, to a certain extent, will light the building without our being compelled to see where the light comes from, especially if some form of reflector is used to throw the rays forward towards the centre, but if there are brackets on piers, or on side walls, it is necessary to keep the width of the nave, that is the distance across from point to point, within certain limits. Standards are sometimes adopted as a method of securing an equal distribution, but they are objectionable for reasons that will follow in considering the height at which the lights are best fixed. There is another course that may well be followed, and that is to use pendants; these, whether hung out from the walls, or directly from the roof, seem the least objectionable idea, for with them we can distribute the candle power as we will, and they may be regulated in height from the floor. A useful practical position for pendants is about in a line centering over the seating space on either side of the middle aisle; any decoration on the walls or roof is little obscured by the glare from them in such a situation.

Of the various kinds of artificial light now available two are most commonly used—electric light and gas. Of acetylene gas I cannot say anything, as it is only a new product comparatively. Candles and oil lamps as general illuminators do not now command very much respect for several reasons, so it will be sufficient to confine any further remarks to the two kinds at first mentioned. Electric light appeals to us all because of the many chances it gives of lighting a place beautifully as well as effectually. Its colour, though rather white and cold as a light, interferes but little with the colours in any decorative work, unlike the strong yellow of oil lamps which combines with and quite alters the hues in painted work. But I find from experience that the chilling feeling of electric light, always exaggerated by the use of white shades and reflectors, can be toned down so as to be quite like a lovely mellow ray of sunshine by using polished copper reflectors. One objection to the use of electric light is its piercing glare, but you can dispose

of this trouble by breaking up the rays, and by carefully selecting the situation and height of the lamps. One way to combine the use of copper reflectors with an effort to multiply the rays in a pendant is to put an inverted saucer-shaped reflector over the lamp, and from this to hang by slender chains a cut glass bowl, close up under the lamp, with the whole surface faceted so that it looks like a transparent cup of diamonds. In speaking of gas for the purpose in view my reference is to incandescent burners, and if these are used there is little to choose between it and electric light, so far as their relation to decoration is concerned. Gas is a slightly warmer-toned light than the other, but in candle power they are nearly equal.

There is another idea that we need to consider before quitting this immediate subject; it is, too, one which affects the whole character of a decorative scheme, and of an architectural composition, as much as the comfort or pleasure of any person who looks at these by artificial light, and it also helps to give dignity or suggest depression to everything that takes place in the building. And this is the level above the floor at which the lights are placed. Keep them too low and they will blind your eyes to all things else, and make the interior seem mean, small and circumscribed. Lift them well up at least 8 ft. above the average level of your eyes, and the building is transformed at once; it becomes open, capacious, free; it has an air of easy repose, and its size you apprehend because that which kept you in oblivion now teaches your open eyes to see.

In a church there are several objects necessary for its complete equipment. These we, as a rule, think of as the furniture. And if the person who has designed a building is not privileged also to design or select all the furniture that is required, he may at least hope that his opinion will be sought regarding it. Now what is there that we may speak of as the flesh, the mind, and the soul of architecture? Surely these are to be found in the mouldings, the carving, the colouring, and the furnishing! Is not decoration, then, in nature always the finish to perfect structure? Therefore let us first have sound and well-studied building, and let us design it, always bearing in mind that the bones are to be in time clothed with a covering beauty—a beauty which shall never hinder nor interfere with, but rather express and more fully interpret all that other beauty of which it is the completion. The various items of furniture are considered essentially ecclesiastically and architecturally; however, in neither sense can the building be considered complete unless colour has been introduced, and that not only upon such furniture. Mouldings and carving we can omit entirely, but not colour. It is of course inevitable that it should be there in a modified way because all materials possess it naturally, but it should be there by design as well as by occurrence.

The use of woven stuffs of all sorts in the decoration of churches is much in need of revival. I do not mean at all to say that this revival has not been tried. For it has, and in the still too few cases where the art of the weaver has again been introduced to serve the needs of the Church much interesting and beautiful work has been done. Now why may not this method of decorating churches be more used? It is a means by which permanent coloured work may be introduced, though it may, with some force, perhaps, be urged that equally good results can be obtained by methods which do not involve the exercise of so much highly skilled capacity. It need not be always so costly as it is now if its use became more general. And we are not obliged to use figure work in all tapestries. But I am inclined to think that such a material should be used rather sparingly, as a hanging, say, behind the font, as a panel in a reredos, or as a frontal for an altar. It would look very fine, too, as a curtaining round the walls of a sanctuary. By tapestry we should mean real tapestry, not the sham material of the wholesale furniture mart. And above all, in using it, we must insist on having good colour, real colour, not dark, morbid, heavy shades, not feeble tints, but bright, cheerful

tones taken from the tints of flowers, or jewels, or sunlit clouds. There may be uses, too, for other woven stuffs; those large curtains, hung in big folds with fine simple lines of curve, which are to be seen as a feature of many a western entrance in Italy are suggestions of what might be done even in England. Where we have most adopted a kind of curtain hanging in England is in the dossal and the wings or riddle hung behind an altar to take the place of any more elaborate work, such as a reredos. Many beautiful effects have been obtained by this method; it is a simple one, and need not be at all costly, and the number of materials that can be used for the purpose is almost unlimited. Curtains, too, may be used with fine effect if well hung, and well chosen for colour, in place of wood screens. There is one thing further—be very careful about the altar frontals. They become part of a decorative idea, and should therefore be designed in keeping with it. There is much room for improvement in embroidery, and each of us can help in this by watching over its production, from the making of the design and the choosing of grounds down to the selection of the kind and colour of the threads, silk or other, or the texture to be obtained by the character and direction of a stitch.

Again, there is the subject, a most important one it is too, which requires much forethought. What shall be the colour scheme in relation to lightness and darkness by which the impression or impressions at which we aim shall be produced. Shall it evoke a bright, cheery, and hearty response of delight in our surroundings? Shall it make us full of joy in the freshness of lovely beauties of colour and form, or must we submit to some sombre gloom full of suggestions of pessimistic distrust? Does the situation, does the climate, the intensity of light, or the soft mistiness of its suppression, permit us to use safely an abundance of bright or deep toned colours, or of whites or greys? For broad ground work we may select a large variety of tones of some few colours. A blue or a gold ground in mosaic work is the traditional course to follow. But in cities of the north we need develop other methods than those proved of so much value by southern experiment, and it seems natural to suggest that a white mosaic ground would be a useful one, especially for buildings in large towns where the light is rather feeble. The necessary warmth and brightness could be introduced in the decoration upon this ground.

These thoughts seem naturally to lead us forward so that we shall turn our attention to decoration as it may be used when applied as a partial scheme. This would mean that we should use very little figure work, but mostly conventional patterns, or moulded and carved work coloured. And they also introduce ideas of a comprehensive treatment of the whole building. Now I will take this part of the subject in a similar order to that observed before.

Windows, and the glass in them have always been most valuable as a means of decorating, or destroying, an ecclesiastical building. They can give us the most beautiful colour it is possible to get by any artificial medium. If stained glass is to be put into the windows we should fight hard against the prevailing custom of introducing into one's building a mixed collection of samples, good and bad, by a variety of designers. Let there be a unity of idea throughout the wholeseries connecting them together as subjects, as colour schemes, and in the general principle of their treatment as several related designs. It is quite possible to accomplish this, even though the first window may be inserted years before the series can be completed, but whatever is done, let the work be stained, not painted glass, and let the design be strictly decorative, strictly conventional, strong in line, flat, having no pictorial shading, and never a shadow.

All particular ideas, all special media, in one decorated building is relative, and the attempt of a general supervision should be to keep each designer in any craft in proper subjection to the one object of the whole scheme. If we are allowed to add applied decoration to the walls and arches let us keep the same

principle of unity always still in view, and this unity is possible best when we do not, as it were, riddle and worry all surfaces with something which calls for notice. To keep a common groundwork and to show plenty of it will help to give a continuity to the prevailing idea of your scheme; or else subdue the ground and connect the related parts with a covering pattern or diaper. The two methods combined aid each other. The restfulness of a plain field, either of white or in colour, with but little applied decoration, helps to counteract the restless activity of thought apparent in the intricacies of meandering scrolls, or the repetition of one idea in spotted diapers. This is but another way of saying take care of the value of your contrasts, as well as of the arrangement of lines, the contours of form, and the quality of colour. It is a pity we do not more realise to what extent we may well omit all moulding and carving if colour on the flat is taught to take the place of these, but it should take their place not as a hypocritical mimic that would savour of theatricism, but rather as a substitute frankly acknowledged in the methods by which it is introduced.

However we may decide to act in detail let us follow the principle already suggested and observe the uses of subjection and accentuation both in detail and in the general treatment. Above all, keep the unity of the two architectural and the three ecclesiastical parts of the building a patent fact, and at the same time let the beauty and value of the work in the chancel exceed that in the nave, and in the chancel concentrate your best efforts upon the treatment of the sanctuary as distinct from, though contiguous with, the choir. With regard to the roofs, ceilings, domes, or vaults, much that I have said concerning the walls applies to them, but as they are more removed from the ordinary eye-level they call for a large vigour and breadth of handling. Notice how clear, how definite and firm are the lines of design in the pattern work from St. Anastasia in Verona, St. Alban Abbey and Chichester Cathedral. In painted figure subjects the same simplicity and readable clearness—lucidity if you will—prevails. The theme may call for the representation of few or many figures, but never in good work is there a single unnecessary one introduced. The endeavour is rather to compress the thought by elimination than to expand it by overgrown profusion. In the mosaic schools of the East and of Italy it was the same. Consider the self-repression, for the sake of clearness, that is evident in the decoration of Sta. Sophia and St. Mark's. Frequently there are simple figures set alone upon the groundwork having little or no connection with each other in design; they depend for their relation upon the idea which their attitude, position, and grouping suggests. Be epigrammatic, speak a volume in a sentence, give a life's history in a sonnet—that is the aim and the attitude that literature suggests to design. And design requires before all things an exercise of repression, restraint, selection, and if it has not passed through the crush-mill of your own merciless criticism it will not stand the test of exposure to the views and tastes of other minds.

A vote of thanks was accorded to the lecturer on the proposition of Mr. J. D. Crace, seconded by Mr. Cole A. Adams.

East-End Housing.—The London County Council propose to clear three areas at Poplar at a cost of £16,000, displacing 269 inhabitants. One of the areas will be turned into a playground. A Home Office enquiry into the scheme was held last week.

The National Gallery.—The report of the director (Sir Edward J. Poynter) on the National Gallery for 1899 has few acquisitions to record, for the purchase of two Rembrandts from Lord de Saumarez absorbed all the available funds. The price paid was £15,050. The hot-water pipes in some of the rooms which, by over-heating, endangered the preservation of the pictures, have been removed to the middle of the floor. As the result of successful experiments, the flaws are to have only a low polish in future.

Professional Practice.

Chester.—The case of *Jones v. Montgomery* was recently heard before Mr. Justice Bucknill and a jury at the Chester Assizes. It was an action by Mr. Arthur E. Jones, architect, Old Bank Buildings, Chester, to recover £207 odd as charges and commission in connection with the re-building of the King's Head Inn, Grosvenor Street, Chester, and the Grotto Inn (formerly known as the Harp and Crown), Bridge Street; the defendant being Mr. Thomas Montgomery, managing director of the Lion Brewery Company, Chester. The defendant not only denied liability but denied that he had instructed plaintiff to prepare the particular plans in question, and further counter-claimed damages because of plaintiff's alleged negligence and want of skill. The judge commenced to sum up, when one of the jurymen had a fit, which caused a painful scene in court. He was removed, and after some delay the parties agreed to take the verdict of the remaining eleven jurymen, and the judge proceeded. He pointed out that the real question at issue was not whether plaintiff was entitled to recover for work done, because the work had not been completed, but whether he was entitled to damages for being prevented from carrying

for 522 infants; on the second, accommodation is provided for 486 juniors; and on the uppermost floor a similar number of seniors can be accommodated—a total of 1,496. In addition to the cloakrooms at the south, west and east of the building, there are others on each landing. Part of the basement is to be used as a laundry and cookery room, and the remainder is taken up with apparatus for the heating and ventilating, which is on the propulsion system.

London.—We give on this page a perspective and first-floor plan of the enlarged Italian Hospital in Queen's Square, Bloomsbury, which was recently opened by the Italian Ambassador (Baron de Renzis di Montanaro). The hospital—which was founded in 1884, and rebuilt 1898-1900 on the same site, but enlarged by the addition of the adjoining house in Devonshire Street—was designed by Mr. T. W. Cutler, F.R.I.B.A. The building is in the style of the Italian Renaissance, with a handsome façade looking into Queen's Square built of red brick and Portland stone. It consists of three floors, and the front facing Devonshire Street is relieved by a dome covered with lead. As will be seen from the plan, the first floor is devoted to male patients, and consists of a large ward warmed and ventilated by open Galton stoves at each end, with the

ITALIAN HOSPITAL, QUEEN SQUARE, LONDON, W.C. THOMAS W. CUTLER, F.R.I.B.A. ARCHITECT.

out work which he was engaged to do under the contract. The jury, after a short retirement, returned into court with a verdict for plaintiff on the full amount claimed—£207, less £71 9s. already paid to plaintiff.

Glasgow.—A new Board School has been erected in Dunard Street from designs by Messrs. H. B. W. Steel and Balfour, architects, Glasgow, at a cost (inclusive of the site) of about £27,000. When the Board purchased the site in Dunard Street, clay was being dug out and manufactured into bricks on the spot where the school now stands, and only a few years ago the district, which is now densely populated, was a grass field known as Sheepmount. When the Glasgow School Board began operations in 1873 the school accommodation was limited to 57,290 places, good, bad, and indifferent; whereas now there is fairly good accommodation in Glasgow schools, including those of the Roman Catholic Church, for 107,733 scholars. The new building is designed exteriorly in the classic style of architecture. It has three floors. On the first are five classrooms, with accommodation

addition of hot-water radiators designed to admit fresh air, which is then warmed and passed into the ward at a low velocity calculated to change the air in each ward three times an hour. There are no hollow linings to collect dirt and dust in the windows, which are so constructed as to allow the ward to be "air-swept." In the ceiling is a large exhaust ventilator for the removal of vitiated air. Admission of fresh air and displacement of foul air are obtained by fanlights hinged at the bottom to fall inwards. The floor is of English oak, tongued and grooved, waxed and polished, and the joints are caulked with mastic. There are no mouldings in any woodwork to accumulate dust, only rounded edges. The ward is lighted by thirty incandescent lamps of 16 candle-power each. In the Devonshire Street wing there is a ward of four beds for surgical cases and four single wards for special cases. The circular staircase is entirely detached from the wards by a cross-ventilated lobby on each side, so that no ward air can be carried from one floor to another. There are two detached sanitary blocks containing bathrooms, w.c.'s, and slop sinks, lined with white-glazed tiles to a height of

FIRST FLOOR PLAN.

ITALIAN HOSPITAL.

4ft. 6in. and lighted by electricity. All appliances are fixed clear above the floor, which can thus be readily cleaned. The wastes from sinks and lavatories run into a gutter in the floor, and the waste from baths (all movable) discharge into a sink let into the floor. The second floor is devoted to female patients, with a ward for eight, a smaller ward for four, two single wards, and a children's ward. Disconnected by a corridor, open to the air, is an isolation ward. Two outside unenclosed lifts are provided to ward floors for coals, dust, soiled linen, &c., to prevent their being carried through the building. The top floor is arranged for the nursing sisters. The chapel is on this floor and forms the finish to the top of the staircase; it is surmounted by the dome. One of the roofs is asphalted and used as an airing ground for patients, with a covered shelter fitted with seats. The staircase and floors are fire-resisting throughout the building; the ceilings are of expanded metal, suspended from an iron and concrete floor, with an air space between for the stoppage of sound or fire. The ground floor consists of entrance hall, rooms for the committee, house surgeon, operating room with accident ward adjoining. There is a patients' lift (7ft. by 3ft.) in the centre of the staircase. The out-patients' department is shut off from the hospital. The basement is devoted to the servants' department, with linen room, heating chamber, wash-house, post-mortem room, and a vaulted mortuary under the roadway.—New front blocks have been added to the Marylebone Workhouse. These face Marylebone Road and stand on the site of the original workhouse infirmary built in 1792. They comprise two double blocks, connected on the ground floor and basement by wards and workrooms, and on the upper floors by light fire-escape bridges. With the completion of a comparatively small block of buildings for able-bodied men, and the enlargement of the receiving wards, the workhouse will be fully re-constructed. The two new blocks are, with a small exception, exactly similar in arrangement. Cheerful airing-yards are provided both at the front and in the rear of the buildings, the former being laid out with gravelled paths and flower-beds, and the latter paved. The buildings have been erected from the designs and under the superintendence of Mr. Alfred Saxon Snell, at a cost of £52,000.

ITALIAN RENAISSANCE

DETAIL.*

BY G. A. T. MIDDLETON, A.R.I.B.A.,
M.S.A.

"NOWHERE did the exuberant fancy of the early Renaissance architects find such free play as in the enrichments of their buildings. Founding their designs mainly upon the scroll-work of ancient Rome, in low relief, they developed a treatment which, while of infinite variety, is always recognizable as that of their age and country. Sometimes formal, sometimes free, always conventional, always subdued sufficiently not to interfere with the general design which it decorates, it is uniformly pleasing. Panels and pilasters are freely ornamented with scrolls in which the acanthus is largely, but by no means exclusively used, other leaves and flowers being introduced, conventionally treated in a highly decorative way, to fill, but not to crowd, the space available."

Such was the judgment passed a few years ago, before Italy had been visited, based upon photographs, drawings, and casts, and upon the few small examples of original work to be found in South Kensington Museum. Since that time Italy has been visited with the express intention of studying closely the ornamental detail of the period of the architectural Renaissance *in situ*, and of making measured drawings of selected examples of it for publication in book form ("Architectural Details of the Italian Renaissance," by G. A. T. Middleton and R. W. Carden. London: Batsford); examples selected as much for variety of treatment as for their beauty; and a modification of judgment has been the natural result. But a moderate modification only has been necessary.

The original judgment, it will be noticed, was passed upon the earlier work only, it being acknowledged then, as it is more fully recognized now, that the detail of the later period of the Renaissance, in Italy as elsewhere, was wanting in imagination, in the underlying spirit of conception and design, though its grandeur and its suitability to the buildings which it serves to decorate could not possibly be appreciated till the buildings themselves had been seen. It was the scroll-work of the later rather than the earlier period, however, which was based upon the scroll-work of ancient Rome in any deliberate sense, as it was the buildings of the later period which more nearly followed Roman models. The earlier workers may have been influenced somewhat by the examples of ancient Roman craftsmanship around them, as they unquestionably used the ordinary Roman details, such as the leaf and dart enrichment; but they appear to have been also influenced by Byzantine tradition, and as this was itself based upon the Roman and its predecessor the Greek, we may almost be justified in recognizing a continuity of classic tradition, so that the early Renaissance, so far as its ornament was concerned at any rate, was a native descendant and true revival of the classic spirit as opposed to the copyism of the classic letter which came later on. The tradition had in fact been kept alive in the treatment of the goldsmith's work if not in architectural carving, being modified to suit the material in which the goldsmiths wrought; and, as has been pointed out by Mr. W. J. Anderson in the book which he published some four years ago ("The Architecture of the Renaissance in Italy," London: Batsford), the enrichments of the earlier Renaissance buildings were such as would be designed by jewellers rather than by marble masons.

It has become customary of late to consider the Renaissance architecture of Italy territorially as of three great types, Florentine, Roman, and Venetian, each with its own broad distinctive characteristics, this division being accounted for alike by geographical and

political considerations, and explained in a masterly manner by Mr. Anderson; but it seems to be hardly possible to differentiate territorially in the same broad way about the ornamental details. In Florence, in Rome, and in Venice, to say nothing of the smaller towns, there is the same low relief carving inspired by designers in embossed, engraved, and jewelled metal work, the local differences being of a comparatively minor character and generally due either to some peculiarity in the available material in which the work had to be executed, or to the idiosyncrasy of some particular designer. Thus, speaking generally, the intention seems in all cases to have been to fill the space to be occupied with ornament in a manner which should not obtrude itself or detract from the general design of the building or feature which it decorated, while giving an impression of surface texture when viewed from a distance, and while being also most pleasing in itself when inspected closely. Covering the whole space well, and raised upon a flat background, the carved decoration generally takes the form of leaves and flowers, with animals and birds occasionally interspersed, joined together by fine filaments in even lower relief than the principal masses, and all arranged in the form of graceful scrolls. In vertical panels and pilaster strips there is frequently a central stem rising from a vase, the pattern being symmetrical, but this treatment is by no means universal. As a rule, the face of the panel is sunk, and the relief of the ornamentation rarely exceeds the depth of the sinking—though this remark does not apply to frieze and tomb enrichments, which are rarely sunk within panels; but even within these limits there is considerable undercutting to give the necessary depth of shadow, this being practicable in so hard a material as white marble, which is almost invariably the material used.

Another instance of the influence of the goldsmith is to be found in the frequent introduction along the central stems of vertical panels, of vases and cups, themselves enriched with bead and leaf ornamentation. Superficially similar to this, but essentially different in reality, is the copyism in stone of turned and carved work in high relief, such as is suitable in woodwork—a style of ornament which is comparatively rare in Italy, but of which South Kensington Museum contains a fine example in a doorway from a palace at Genoa, which is of considerable importance, as upon it is based a good deal of the earlier Renaissance carving of France and Belgium.

The presence of scroll-work ornament based upon either the acanthus or the anthemion is comparatively rare in the earlier work, though common in that of the unimaginative later period, when the leaves are generally found to be conjoined, delicacy giving way to richness and to gradually increasing obtuseness. In place of these motifs, of classic origin, are found representations of natural fruit, the olive and the grape predominating, of natural flowers such as the poppy, of cereals such as wheat and barley, and of leaves such as those of the oak and vine. Birds are introduced with tolerable frequency, usually differing but slightly from the natural form; but, speaking generally, when dealing with animate life the grotesque is much more common than the natural treatment. When used as sculpture, the human figure is correctly rendered, but when employed in conjunction with scroll-work considerable anatomical liberties are taken for the sake of decorative treatment, and very beautiful, as a rule, is the result. Beauty, however, may hardly be said to be characteristic of the numerous dolphins and dragons with which the fertile imagination of the craftsman would often enrich his composition to its great advantage as a whole.

It may be noticed at this point that the dolphin and the scallop shell are found as enrichments in inland as well as seaside towns. Indeed the only enrichment which appears to be confined almost entirely to one locality is the winged cupid's head, which is frequently seen in Rome and but rarely elsewhere; while the comparative coarseness of much of the

detail in Bologna is mainly due to the use there of terra-cotta in place of marble.

Besides the low relief decoration, of which there is a very large amount, there is also a smaller proportion of incised and inlaid work. The inlay affected for external decoration appears to be metallic lead, which has a very good effect indeed against the white marble in which it is set; while a black composition is frequently used in a similar way where it is under cover. Whichever be employed, the pattern is almost invariably a repeating one, based upon a leaf of some kind, and the band of enrichment narrow.

The mouldings, whether of cornices, door jambs, panels, or anything else, come as a revelation to one who has hitherto studied from books alone and has been inclined to think that the Italian Renaissance, in this respect at least, was bound within the strict traditions of the Orders. So it may have been a hundred years or so later than the period which we are now considering; but the fertile artists of the early period disdained to be bound by hard and fast rules—or probably were unacquainted with them—and evolved or developed just such mouldings as would give the effect they wished to the executed work. It must be admitted at once that, when drawn upon paper, the contours are not always pleasing; but then the mouldings were not intended to be seen in contour. Here more than anywhere else has the general idea of Italian work been wrong, that being most generally commended which has conformed most closely to the "Orders" as laid down by Chambers and Vignola, whereas that is the least commendable, the least original, the least adaptable to varied circumstances. It is not too much to say that the art of mouldings, as understood by the workers of the early school of the Italian Renaissance, needs to be releant, and that from the craftsman's and not from the draughtsman's standpoint.

In the enrichment of mouldings, however, classic forms were closely followed. The egg and dart, the egg and tongue, the leaf and tongue, the bead and fillet and the dentil, all recur again and again, often varied in some small particular, it is true, but also often of almost Roman purity—evidence that, given certain mouldings, such as the ovolo and cyma, the Greeks and Romans had evolved the most satisfactory enrichment for them, and that this fact was insensibly admitted by their successors of the Renaissance, to whom they had been handed down with scarcely a break of continuity.

In point of decorative importance the metal work of Italy does not rank much behind the carving, if at all. Of the cast bronze work it is not necessary to say much, as the principal examples, such as the gates to Sansovino's Loggia and the well-heads in the courtyard of the Doge's Palace, both at Venice, are well known and universally admired for the marvellous workmanship they display as well as for their beauty, in spite of the redundancy of ill-connected ornament. But of the wrought-iron work it is different, inasmuch as there is a great deal of it of which but little has been illustrated, while the collections at the Birmingham and the South Kensington Museums are by no means so well known as they deserve to be. And this iron is remarkably well worth studying, differing in some important respects from the ironwork of other countries and of other dates, and from that of Italy itself in the later period. In this it follows much the same course as does the carving, the earlier being the more original, instinct with inspiration, and the later conforming more to ordinarily accepted precepts and comparatively tame even when beautiful. After careful consideration, and recognizing the origin of the earlier carved detail, one is irresistibly driven to the conclusion that the source of the patterns of the early ironwork is to be found in the twisted wire ornaments of the goldsmith, so very much of it being the natural outcome of the use of the pliers and the pincers rather than the hammer. Much of it is of great intricacy and curiously unconstructional, and yet of a character such

*A paper read before the Society of Architects on March 22nd, 1900.

as would be perfectly permissible, aesthetically speaking, if executed in wire and on a much smaller scale.

Of the Renaissance enrichments generally, and particularly those of the period now mainly under consideration, it has been said that they are liable to be degraded—to be used as patterns for mere embroidery. As to whether this be degradation there may very well be two opinions, for a well-designed home should be furnished with well-designed accessories, and the result of using designs based on good models would be more likely to elevate the accessories than to debase the models; but whatever may be said upon this point it cannot be questioned that these enrichments embellish the buildings to which they are applied most suitably, most unobtrusively, and altogether admirably.

Builders' Notes.

The Builders' Clerks' Benevolent Institution held its twenty-second annual dinner at the Holborn Restaurant on March 20th, when the president (Mr. Henry Holloway) occupied the chair.

Cartwright Memorial Hall, Bradford.—Messrs. Simpson and Allen, the architects of this building, desire not to have the design interfered with and it has been decided to respect this wish. If the full design and details meet with Lord Masham's approval, a special meeting of the City Council will be called to deal with the financial part of the scheme; for it will be remembered that the tenders considerably exceed the amount offered by Lord Masham for the memorial. It is expected that the foundation stone will be laid in May.

New Building By-laws for Cardiff.—For more than twenty years the Cardiff Corporation has been endeavouring to obtain the assent of the Local Government Board to certain street and building by-laws which they were desirous of adopting. Probably in the early stages of their work the municipality was looked upon as a revolutionary one—they wanted it enacted that every new street should be at least 40ft. wide, besides a hundred and one more advanced improvements. Year by year the marginal objections have become less, and now they have been sanctioned.

The Yarmouth Amalgamated Society of Carpenters and Joiners held its annual dinner recently, when Mr. Councillor Beech presided. Mr. Chasteney gave "Success to the Building Trade," observing that since their last meeting their chairman had fought another municipal election and was returned as the builders' representative at the head of the poll. Mr. Beech, responding, said he had it on excellent authority that the Midland and Great Northern Railway were contemplating building a new station at Yarmouth, which would cost £200,000. They were also going to erect a large hotel, with 200 bedrooms, and required more land, if the Corporation were willing to dispose of it.

Apportioned Cost of Public Street Works.—The appeal case of *Stock v. Meakin*, heard before the Court of Appeal on February 27th and March 5th, raised a question of some interest and importance under the Private Street Works Act of 1892, namely, whether the sum finally apportioned as payable by the owner of premises fronting a street, in respect of works (such as sewers) executed in the street by the local authority, becomes a charge upon the premises as from the date of the completion of the works, or only as from the date of the final apportionment of the expenses of the works among the various owners of premises abutting on the street. Lord Justice Vaughan Williams, delivering the judgment of the Court on March 19th, dismissed the appeal.

Building at South Kirkby, Wakefield.—The South Kirby Colliery Company are about to erect 134 houses in the district of White

Apron Street. They are to be formed into streets, properly drained, flagged, and macadamised, and many of them will be provided with three bedrooms and kitchen garden, as well as the other conveniences attached to an ordinary working-man's house. They will be under the authority of the Hemsworth District Council and will have a good supply of the Barnsley water. It is intended to erect a large store in the centre. The execution of this scheme is in the hands of Messrs. Garside and Pennington, architects, of Pontefract, Castleford, and Selby. The same company have land in Mill Lane, South Kirkby, upon which another sixty or seventy houses are shortly to be built.

The Strand Improvement.—At the Surveyors' Institution, Westminster, on Thursday last, Mr. J. Green (Weatherall and Green), the valuer appointed by the Local Government Board, held a preliminary enquiry to determine the value of the property of the betterment area in the scheme of the Holborn and Strand improvement. The case of the leaseholders was first considered, and Mr. Green stated he was instructed for the purpose of that valuation to value (1) the site value of the property, (2) the value of the land and buildings as a whole, (3) the interest of the owner, and (4) the interest of the leaseholder, whose lease at the time of the valuation had twenty-one years to run. He decided that the holders of leases expiring within twenty-one years had no *locus standi*. The majority of the cases had been settled on terms agreed upon with Mr. A. D. Young, the valuer of the Council. The sitting was adjourned.

London County Council.—At the meeting held on Tuesday in last week, the Local Government and Taxation Committee submitted some new by-laws: (1) imposing a penalty not exceeding £5 on employers who do not provide sufficient support to prevent their servants falling off sills when standing on them for the purpose of cleaning or painting windows, when the sills were more than 6ft. from the ground; (2) imposing a penalty not exceeding £1 on the servants themselves for the same offence; (3) prohibiting the use of street flash-lights and night signs, and imposing a penalty not exceeding £5 in case of default; and (4) imposing a similar fine for indecency in the street. These by-laws were approved. The Parliamentary Committee recommended that they should be authorised to insert in the Council's Improvement Bill a clause to provide that the land between the embankment and the Millbank Street to be formed in connection with the Westminster improvement should be laid out as a garden. This was agreed to after some discussion. Tenders amounting to about £107,000 were accepted for the erection of ten blocks of dwellings on the cleared area at Millbank. This will effect a saving of £11,000 on the architect's original estimate of £118,000. The Council decided to instruct the chemist to continue the analysis of the water from the Thames and Lea above the companies' intakes, and of the water drawn from the companies' mains for a further period of six months, and approved the allocation of the sites for the reinstatement on the western plot between the new crescent road and the Strand of the Gaiety Theatre, Gaiety Restaurant, and Messrs. Short's premises, such sites to have an area of about 12,860, 10,450, and 2,100 sq. ft. respectively.

Trades Unions' Dispute: Slander.—A trades union slander case was heard last week at the West Riding Assizes, held at Leeds, before Mr. Justice Bigham. The plaintiffs were five officials of the Leeds centre of the Federated Builders' Labourers' Union, and the defendant was George Belt, the organiser of the Independent Labour Party at Hull. The slander was that at a meeting held on November 1st, at York, the defendant suggested that various moneys sent from Hull through York to Leeds had not been accounted for. Defendant was stated to have said that the accounts were "cooked" at Leeds, and that the plaintiffs had mistaken their vocation, that they were "Jabez Balfours" and ought to be floating bogus companies.—For the defence it was argued that the

occasion was privileged, but his Lordship, holding that the meeting was public, ruled otherwise.—Mr. Scott Fox (for the defendant) then said it was a case which had a very important bearing on the interests of working men throughout the kingdom. In Yorkshire, at the time in question, Leeds had become a dominating power, and York had been for some time rebelling against this. In July, 1899, York started a branch of its own, which the Leeds members did not like. The learned counsel contended that defendant was entitled to comment on the proceedings at the meeting, and suggested that at such meetings there was invariably some vigorous language used.—The jury, after retiring, found a verdict for plaintiffs, with damages one farthing.—His Lordship, in entering judgment, said when a jury returned a verdict with one farthing damages he regarded it as an opinion that the action ought not to have been brought. Accordingly, he should deprive the plaintiffs of costs.

Electric Wiring: an Interesting Case.—The case of *Moody Brothers v. Henley and Co.* was heard before Mr. Justice Ridley and a jury, in the Queen's Bench Division, on Thursday last. This was an action brought by electrical engineers to recover £315 11s. 3d., their charges for an installation of electric lamps and fittings and a dynamo in the defendants' premises. The defendants, who are photographers and colour printers and have premises at Epsom, claimed to set off against the amount claimed damages for the destruction of a building and its contents by fire owing, as it was alleged, to the defective manner in which the installation was carried out. The premises consisted of the main building, or factory, and a building 60 yds. or 70 yds. distant from the main building, containing a studio and a dark room. This was the building which was burnt down. The dark room was constructed of wood and the studio partly of wood and partly of glass. The two rooms were separated by a partition of matchboarding. The dynamo was placed in the main building and a cable was laid to the studio, where there was, among other lamps, an arc projector lamp capable of giving a light of 25,000 candle-power. The cable passed through the floor of the studio and resistance coils were fixed on to the matchboard partition at a distance of 4in. from the matchboard, separated from it by a piece of asbestos. The projector lamp and its fittings were supplied in September, and the fire took place on October 3rd. Professor Boys and other expert witnesses were called, who stated that the installation was, in their opinion, defective because (1) there was no metal guard round the resistance coils; (2) these coils were placed at a distance of less than 10in. from an inflammable material; (3) there was no double pole switch at the dynamo by which the current could be completely shut off from the studio building; and (4) fuses ought to have been placed at the junction of the cable and the wires of the projector lamp. Mr. Witt, on behalf of the plaintiffs, suggested that, if the cause of the fire was connected with the electrical apparatus at all, it was due to the interference with the apparatus by some person after it had been tested by Mr. Moody and Mr. Heron. Mr. H. N. Moody said there was no brick or stone wall in the studio, so that he was obliged to fix the resistance coils to the wooden partition. The air space of 4in. was sufficient, taking into consideration that the lamp was protected by a sheet of asbestos. The lamp was one of Crompton's. The base of it took the shape of a tray sufficient to prevent any pieces that might be detached from the carbons from falling on to the floor. The following questions were put to the jury to which the answers are appended: Was the fire due to the action of the electrical apparatus? Answer.—"Yes." If so, was the apparatus constructed in an improper or unskilful manner? Answer.—"No." The jury added that in their opinion the fire was due to some interference with the apparatus after the departure of Mr. Moody and his partner.—Judgment was entered on this finding for the plaintiffs, a stay of execution being granted pending an appeal.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Roofing Tiles.

LONDON, E.C.—L. O. and Co. write: "Who are the manufacturers of the 'Longport' and 'Victoria' roofing tiles? Is there a book of reference giving information as to the names of manufacturers of goods specified by name or brand?"

Messrs. Boulton and Co., Midland Tileries, Longport, make the "Longport" roofing tiles. We cannot trace the makers of "Victoria" tiles. We do not know of any book giving the names of manufacturers of goods specified by name or brand. Lockwood's or Laxton's "Price Book" might be of use; either can be had from B. T. Batsford, 94, High Holborn, W.C., price 3s. 4d. each

Legal Books for Architects.

ARMAGH.—H. C. P. writes: "I should be glad to know the price of the following books, and where I can obtain them:—'The Architect's Legal Handbook,' 'Hudson on Building Contracts,' 'The Specific Performance of Contracts.'"

"The Architect's Legal Handbook" is now quite obsolete, and has been out of print for some two or three years. "Hudson on Building Contracts" will cost £2 5s. nett, and may be obtained from B. T. Batsford, 94, High Holborn, W.C. "The Specific Performance of Contracts" is published by Sweet and Maxwell, 3, Chancery Lane, W.C., at 5s. nett.

Measuring Mouldings.

HEREFORD.—H. S. writes: "In measuring and making surveys of old churches I find a difficulty in taking the correct forms and measuring the outlines of the mouldings to caps, bases, &c., of columns. I should like to know the best method of doing this."

When the mouldings are not too undercut, the best method of obtaining accurate drawings of them is to get a strip of lead about $\frac{1}{2}$ in. wide (any plumber will cut this for you) and carefully press it into the curves and hollows of the mouldings. When this is done the lead strip may be laid upon a sheet of paper, and with a pencil follow the shape of it, which will accurately give you the form required. Great care, however, must be taken that the lead is not bent in removing it.

H. F. W.

Alternating Gear for Charging Sewage Filters.

PARSONSTOWN.—OAR writes: "I should be glad to know the names and addresses of firms who manufacture self-acting alternating gear for charging filters in connection with a septic tank. The installation is for a workhouse with a maximum number of inmates of 500, and simplicity in working is most essential."

Messrs. Cameron, Commin and Martin, 7 and 8, Bedford Circus, Exeter, are patentees and manufacturers of alternating gear for charging filters in connection with a septic tank, suitable for both country houses and towns. Messrs. Adams and Co., 7, Old Queen Street, Westminster, London, S.W., are also patentees and manufacturers of self-acting alternating gear for sewage tanks and filters, together with other necessary fittings required in connection with biological sewage purification.

T. E. C.

Draining a Cow-shed.

STOURBRIDGE.—SURVEYOR writes: "Which is the best way of draining a cow-shed? In a case under my charge the liquid manure settles in the pipes, which are continually

stopping up. There is a gully fixed outside the cow-shed, on to which a pipe running under the stalls to the back of the cows delivers. I am told that the drain ($\frac{1}{2}$ in.) from the gully has a fall to the pipe of nearly $\frac{1}{2}$ in."

The drainage arrangements mentioned require reconstruction. No traps, gulleys or underground drains should be permitted in a cow-shed, all urine and other refuse liquids being removed to the outside of the building by means of surface channels. The floor and channels can then be thoroughly cleaned by hand, and the whole maintained in a satisfactory condition. The best method of draining a cow-shed is to provide a granite concrete floor, carefully laid to proper falls and having a shallow channel at the rear of the stalls, which should be carried through the external wall so as to discharge over a trapped gully outside. The gully should be of the type known as a "stable" gully, and provided with a perforated catch-basket immediately under the surface grating to retain any straw or other solids, instead of allowing them to pass into the drain. Several well-known firms of concrete workers make a speciality of paving and surface channelling for cow-houses, and it is in every way desirable to have such work executed by them.

T. E. C.

Valuing Building Stock.

LITTLEHAMPTON.—INCOME TAX writes: "In preparing a general balance sheet of liabilities and assets, should stock be valued at market price or not?"

The value of your building stock must be put down at that which it is worth to you, and, consequently, it varies to a certain extent with the market price; but no one could be expected to place his stock at the market value on a day of any sudden fluctuation. If a man possesses that business acuteness to habitually purchase at the cheapest market and in the most favourable season, it would be wrong, of course, to put a value on these goods applicable to the possibly highest market another time. Moreover, a certain allowance must always be made for various considerations, including expense and waste consequent upon marketing, &c.; and the more general figure for adoption in such a case as your own for the purpose stated in your former query (see page 116 of last week's issue) is about 20 per cent. below market price.

C. BRAND.

Adjoining Owners.

LONDON, E.C.—F. D. writes: "I have had some plans for offices and warehouse disapproved by an Urban District Council, solely on account of the adjoining owner on the north side withholding his consent (the Council requesting me to obtain his consent) to my coming forward to the building line, already fixed by the adjoining owner on the south side. The adjoining owner on the north side seeing his opportunity, and evidently knowing the Council will not approve the plans without his consent first being obtained, asks of the building owner practically £400 for his consent; and to this impudent demand the building owner will not agree. Notwithstanding these facts, which have been put before them, the Council still disapprove the plans, though they admit these comply with their by-laws in every other respect. (1) Can I go to an appeal court? (2) If I build without the Council's approval, can they pull down such new work as may have been built, or can they only withhold their final certificate at completion? (3) Assuming I do not build a building, can I build a 10ft. high division wall between my client's property and the adjoining owner's property without asking the Council's approval?"

(1) You have no remedy except an action at law, and there appears to be no ground for that. (2) Under section 156 of the Public Health Act, 1875, the building cannot be brought forward beyond the front of the building on either side without the written consent of the urban authority, who can, under section 158, pull down any work so built without such consent. (3) Probably you could do so, but it depends upon what the by-laws are.

G. H. B.

Under Discussion.

Mediaeval Tithe Barns.

At the concluding meeting of the session of the Birmingham Archaeological Society on March 21st, Mr. F. B. Andrews, A.R.I.B.A., read a paper on "Mediaeval Tithe Barns." He stated that the English monastic barns might doubtless be traced to the Roman nubilarium, which was a roofed structure, partly enclosed at the sides, to receive and protect crops from the weather. As the land was developed they increased in number and size, and these buildings received not only tithe payments but rental payments. It was only in later days that they came to be known under the general name of tithe barns. Some were of enormous extent, that attached to Beaulieu Abbey (Hants) enclosing a floor space of no less than 7,000 sq. ft., while on the Continent there were some of even greater dimensions. Each monastery and religious house had its chief barn, and smaller barns were attached to every parish. Mr. Andrews gave information relating to many barns which still existed in Worcestershire, Gloucestershire, and other parts of the country, the lecture being illustrated by lantern slides.

American Workshops.

Mr. H. S. Jefferies, a vice-president, read a paper on American workshops before a recent meeting of the Ipswich Engineering Society founded on a visit he paid to the States about two-and-a-half years ago. He said: Generally, all the works throughout struck me as being extremely light, airy, and cleanly kept. Nearly all the large works are provided with washing-rooms for the workmen. These are as a rule large rooms at the works entrance fitted with troughs which are filled with warm water just before the men finish work. Most American shops are extremely well served with electric overhead cranes, varying from five tons to 100 tons lifting capacity, and travelling up to 300ft. per minute. These cranes were made by Sellars, the Shaw Co. and the Morgan Co. In the forge departments I especially noticed the excellent work that was being done under the drop stamping hammers. The boiler work I saw in the States was certainly not up to the standard of this country. One cannot meet the master and principals of American factories without being immensely struck with the vast amount of work and energy they put into their business. In the States many look on their work as the means and end of existence, and seem to understand neither the necessity nor the enjoyment of recreation. They have learnt the pleasure of successful hard work, but they do not seem to appreciate that this is not the only object in life. In nearly all the works I was in the standard hours of work were 60 per week, from 7 to 12 and 1 to 6. No Saturday half-holiday. The Americans are born improvers, as the American patent records prove. They are always ready to try improvements, and are never afraid to give a trial to new ideas and this characteristic is one reason for the success in life; the mere fact of many of their new ideas turning out failures does not discourage them from trying others. In considering the question of American competition I will first mention the points in which I consider the American manufacturer at present has an advantage over his English competitor. These points are, I think, an unlimited supply of cheaper raw material and fuel, and cheaper transport; in many cases better arranged and equipped workshops, and more up-to-date tools; and, finally, a higher rate of output from their workmen. Many of our factories here have been established a long time, and, although we cannot pull all our shops completely down and rebuild them throughout according to the latest ideas, we can keep them properly arranged, and see that our tools are kept up-to-date, and that the work in our factories is properly organised and that the best methods of working are adopted; and I also firmly believe that the British workman can do every bit as good a day's work as his American cousin.

Bricks and Mortar.

APHORISM FOR THE WEEK.

*"Suburban villas, highway-side retreats,
That dread the encroachment of our growing
streets,
Tight boxes, neatly sashed, and in a blaze,
With all a July sun's collected rays,
Delight the citizen, who, gasping there,
Breathes clouds of dust, and calls it country
air.—COWPER.*

Our Inset Plates.

THE cottages at East Hoathly, Sussex, for J. Compton Rickett, D.L., M.P., are built upon the beautiful estate belonging to Burham House, and are practically in the centre of an old orchard. The materials used for the exterior are red local tiles and rough-cast. The materials used in the house at Fleet, Hants, are stone, white rough-cast, and green Westmorland slates. The large room is to be panelled 7ft. high, with a brown canvas frieze above to receive stencilling in soft colour. The inglenook is to be under a low, circular stone arch, and will be lined out with deep red rubber bricks. The foregoing buildings have been designed by Messrs. Hall, Cooper and Davis, architects, of Scarborough.

In Danger of Destruction.

A NEWCASTLE correspondent gives us some particulars of the threatened destruction of the picturesque village of Runswick, on the north-east coast, through the landslide which occurred on the 27th of last month. In a letter published in the "Whitby Gazette," and signed on behalf of the inhabitants of the village, Mr. Sayer says: "Already the cart-road leading to the beach is impassable, and one old building has been completely demolished. Large and ominous fissures, reaching in two cases to the very doors of the houses, have shown themselves in many places; and it is impossible to doubt that unless a strong sea-wall is built—and built quickly—our quaint old village is doomed. . . . Meetings have been held, and an estimate obtained of the probable cost of such a sea-wall as we have indicated. This estimate amounts to £500, a sum which is utterly beyond our unaided means to raise. We have, however, collected the sum of £68 amongst ourselves, but this exhausts our capabilities, and unless our friends come to our help our homes will be lost to us, and one of the few remaining old-world villages on the north east coast will cease to exist. We know that the present is an unpropitious time to appeal to the public for pecuniary assistance, but immediate action is absolutely necessary if our village is to be spared, and we are compelled, therefore, to make this appeal to the generosity of our friends." We feel sure that the editor of the "Whitby Gazette" will be happy to receive any sums which interested readers may care to subscribe towards this most deserving fund.

"Punch."

THERE are many large improvement schemes now in progress in London, but the comparatively small scheme of alterations at St. Bride's Avenue, Fleet Street, deserves mention, because it will shortly be the cause of the disappearance of Mr. Punch's old publishing office. This little avenue, which gives the only view of St. Bride's Church from Fleet Street, was constructed with some architectural style, and considerable éclat, after a fire in 1825. Until that year St. Bride's was so closely invested with houses that parishioners who wished to admire their church had to take a walk to Blackfriars Bridge to see it. Flaxman opposed the making of the avenue, holding that Wren's church was "an ugly thing, and better hid," but that is not the opinion of architects and plain folk. Richardson, the novelist, lies under one of the pews.

The Homeric House.

MR. MYRES read an interesting paper on the Homeric House at the last meeting of the Hellenic Society. The author, in the opinion of most of those present, succeeded in showing that the details of the house of Ulysses given in the Odyssey correspond fairly closely with the palaces of Mycenæ and Tiryns discovered by Schliemann. It follows, therefore, that the architecture which Homer had before his mind's eye was Mycenaean rather than Hellenic. But to go from this, as some would have us do, to the conclusion that the culture of the Homeric age was that which we call Mycenaean is too great a jump. Architecture is an art which evolves very slowly, and its memorials last long after the civilisation which inspires it has perished. The gigantic stone buildings found in different Polynesian islands, for instance, were certainly not placed there by the ancestors of the present inhabitants. How the ruins of the houses of the military orders in Rhodes and Malta will some day puzzle the antiquaries of the future! The Mycenaean civilisation is, however, itself a puzzle. All that we really know about it is that somewhere between 2000 and 1500 B.C. a people took possession of Greece and the isles of the Ægean who possessed a civilisation a great deal higher than that of the natives. Although they were not acquainted until later with the use of iron, they were more advanced than most peoples who have not emerged from the bronze age. They built stately palaces with walls of enormous stones, showed great skill in architecture, and even fortification, and a considerable knowledge of painting and sculpture. They engraved gems, used gold, silver, amber, and lapis lazuli for ornaments, and buried their dead in very elaborate tombs. When dispossessed by the Dorian invasion, a good many of them seem to have betaken themselves to Italy, where they were afterwards known as the Etruscans. Others went to Asia Minor, where they laid the foundation of the later Ionian civilisation. The wonder is where these people can have come from. The Swedish scholar, Professor Montelius, thinks they reached Greece from the shores of Caria, where graves of the same kind as the Mycenaean have been found. He also thinks that they were influenced by the Hittite civilisation. As we have no Hittite remains so early as those of Mycenæ, it is difficult to compare them; but those of a later date which have come down to us are in every way ruder and less artistic than the spoils of Mycenæ and Tiryns.

Exeter Guildhall.

AN Exeter correspondent sends us a cutting from a local newspaper referring to the work of restoring the Guildhall front, and says in the letter accompanying it: "Our grand old Guildhall front has now been boxed up with floor boards, so that it is impossible to see what is being done to it, or what will be done, until this packing-case-like covering be removed. Instead of consulting our cathedral architect, Mr. E. H. Harbottle, of this city, in the matter, the City Council handed the restoration over to Mr. Donald Cameron (of septic tank fame), our city surveyor, who does not profess to have the remotest idea of architecture. He gives it, in turn, to the Society for the Protection of Ancient Buildings, who, you may read in the paragraph marked, are 'architects' and 'experts'! The 'local sculptor' who has just commenced the work for them has never, to my knowledge, ever carried out the restoration of the stonework of any old building before; so that, one way and another, the second chief glory of our ancient city seems in a sore sort of state!" We note, however, that the writer of the paragraph mentioned concludes with these words: "I do not think there is a likelihood of any vandalistic treatment of the old building, and hope that when the present wooden cage has been removed there will be nothing more than renewal visible." The Society for the Preservation of Ancient Buildings has done excellent restoration work in the past, and it may fairly be taken for granted that they will, contrary to our correspondent's views, carry out the work in a manner worthy of the reputation they have acquired.

Our Ugly Capital.

"Is London unlovely; if so, does it matter very much; and what can be done to make this great city beautiful?" These three questions Mr. Whiteing (the author of "No. 5, John Street") set himself to answer last week at a meeting in the Passmore-Edwards settlement, Tavistock Place, W.C. Ugliness, he reminded his audience, was a relative expression, and dealing with London by way of contrast he pronounced it, with the solitary exception of Madrid, the ugliest city in Europe; yea, of the whole world. Compared with Paris, it fell far short for beauty in architecture, civic arrangement, or cleanliness. Dealing with the latter point, he asked why our streets were not cleansed on Sundays, as they were in Paris. The objection that it would involve Sunday labour was mere sentimentality. In the small but important matter of lamp-posts, too, we were disgracefully behind the Parisians. The latter provided standards for which it could be claimed that they were ornamental as well as useful. The eyes of Londoners were, on the other hand, confronted with a "groggy" looking structures that always seemed to be qualifying for the waste-iron merchant (attention to this fact was drawn in our "On Reflection" column a short time ago).

Remedies.

But what was to be done to make London more attractive? The lecturer recalled the fact that Mr. Howard would have them get rid of London altogether. That gentleman's "Garden City" scheme was ingenious and suggestive, but he regretted he could say no more of it at present. Mr. Walter Crane fathered a scheme which could not be regarded as one for the immediate present. His idea was to separate each of the new boroughs by belts of trees and shrubs, so that when one looked down upon them from a balloon they would see the thickly-populated districts of London intersected by immense masses of foliage. That proposal was, he feared, doomed, because it would not carry the London ratepayer with it. Curiously enough, however, there were not wanting artists of the front rank who cried "Leave London alone." He heard Mr. Pennell declare that London was the loveliest city in existence. Why? Because, forsooth, it had a natural, hazy mist, partly smoke and partly damp, invariably hanging over it. Foreigners who came here revelled, according to Mr. Pennell, in this exquisite mist. The narrow streets were charming—Fetter and Chancery Lanes and other similar thoroughfares were, despite all the uncharitable language they provoked from passing Jehus, simply incomparable. None of the schemes he had referred to were, he thought, possible at present. But there was a compromise, and that was to empower or compel—for local authorities did nothing until they were compelled—vestries and other governing bodies to bring about the beautifying of the areas under their charge. The duty of the local authorities towards beauty had never been fully realised; there had always been a shamefaced way in doing anything that tended towards it. Vestries, in fact, had evinced great jubilation when a thing had been done cheaply, when nothing was "wasted" on adornments. He held it to be the duty of the citizens to make their representatives feel, as the people of the Italian Republic felt, that there was a great duty cast upon them in this matter. With men acting on local bodies in the spirit he had indicated, they would not have such grievous eye-sores as the Cobden statue in Camden Town. Instead of obtaining designs from the most competent sculptors, the order for the erection of the memorial was placed in the hands of a local grave-stone mason, who produced a statue that might be taken for that of a retired publican. But Camden Town did not stand alone. Trafalgar Square statues were, artistically speaking, no better, considering the eminence of the heroes they commemorated. Concluding, Mr. Whiteing insisted that, if they could only infuse into vestrymen a spirit of reform, London would become the glory of the British race in more senses than one.

Correspondence.

Ellipse by Compasses.

To the Editor of THE BUILDERS' JOURNAL.

ASHTON-UNDER-LYNE.

SIR,—In reply to Mr. Ramm's communication in your issue for March 21st I beg to say that I am willing to comply with his proposal, and have forwarded to him my address. In doing so, I have stipulated that Mr. Ramm shall employ only one of the two methods already illustrated and that the lines shall be drawn as fine as possible consistent with clearness. I do not, however, anticipate that the result will be of any service to your readers, as presumably they will not have the opportunity of inspecting Mr. Ramm's *full-size* figure with any points of difference that I may find. Those of your readers who may have studied Mr. Ramm's methods and the criticisms thereon may easily prove for themselves whether or no the author is correct in claiming that the result is a *true ellipse*; and so far as I am concerned that is the question at issue.—Yours truly, J. A. PERCIVAL.

The Architectural Museum, Westminster.

To the Editor of THE BUILDERS' JOURNAL.

EXETER.

SIR,—It is some years since I had an opportunity of visiting this most useful museum, but I possess two of its very handy guides or catalogues, both of them published at one shilling. The earliest is dated 1877 and is entitled "Royal Architectural Museum. Catalogue of Collection: With a Guide to the Museum by Sir G. Gilbert Scott, R.A." This brochure contains 76 pages. The second, which is rather smaller (about 24 pages), but is spiritedly illustrated, has on its outer cover:—"Royal Architectural Museum, Tuffon Street, near Dean's Yard, Westminster. Caskets and Jewels: a Visit to the Architectural Museum written for students by John P. Seddon, F.R.I.B.A. 'Our Own Casket,' with illustrations from photographs and copies of sketches by T. Raffles Davison." It is dated 1884.—Yours obediently, H. H.

Portland Cement.

To the Editor of THE BUILDERS' JOURNAL.

GRAVESEND.

SIR,—Mr. W. Day, in his otherwise interesting paper on "Portland Cement," published in your issue for March 14th, has got somewhat mixed in his statements. He writes of me as the *late* Mr. I. C. Johnson, and that I left the country and *died abroad*. I am still in the country and am still alive, although some way on in my ninetieth year. I am by the trade recognised as the oldest cement maker and the inventor of Portland cement *proper*, and patentee of three appliances.

I am not aware that it is of any public importance as to whether I am alive or dead but if you should think it worth while to insert a paragraph, by way of correction, some readers of your valuable paper may be edified by it.—Yours obediently, I. C. JOHNSON.

[Mr. Johnson sends us a copy of the "Abstainers' Advocate" for November, 1898, giving an illustrated account of his life. We note that he first introduced the manufacture of his cement to the firm of J. B. White and Sons, and afterwards started on his own account on the Medway.—Ed.]

"A Doomed Church."

To the Editor of THE BUILDERS' JOURNAL.

EXETER.

SIR,—Under this heading "C. G. H.," of Richmond, in your issue of February 28th, whilst correcting me upon a topographical point, falls into error himself. He writes, when the site for St. Pancras Station was cleared, "the church and graveyard" I referred to "were destroyed." This is inaccurate. The church in question, situated in the New Road (now Euston Road), was known as St. Luke's. Its nominal west end and spired tower abutted the New Road, and private houses stood

against its north and south sides. It was removed *in toto* in 1866 or thereabouts, but no graveyard was destroyed, as it possessed none! "C. G. H.," in his suburban retreat at Richmond, has evidently mixed up in his head the graveyards of two other churches not far from St. Luke's, namely, those of St. Pancras and of St. Giles-in-the-Fields, whose burial grounds adjoined one another. The disinterred coffins from these had previously (about the year 1864) been reverently removed by Mr. Titford, undertaker, of Euston Road.

It was the large district known as Agar Town—not the actual parish of St. Pancras—that was practically demolished by the railway company. Edward Walford, in his "Old and New London," describes St. Pancras as "the mother of which Camden, Kentish, Agar, and Somers Towns may be said to be the offspring." As a matter of actual fact, not only do the few streets "C. G. H.," mentions still represent St. Pancras, but, the same author tells us, a third of Highgate and all Tottenham Court Road and its immediate neighbourhood are included in this enormous parish.

Mr. Walford speaks "of the great clearance of houses which was effected in this locality by the formation of the Midland Railway. The district which is—or was—known as Agar Town consisted mostly of small tenements of the lower class, named after one Mr. William Agar (or, as he was commonly called, "Councillor Agar"), an eccentric and miserly lawyer, to whom the site was let on a short lease for building purposes about the year 1840. Mr. F. Williams in his "History of the Midland Railway" tells us that for St. Pancras passenger station alone a church and seven streets of three thousand houses were swept away. He draws a dreary picture of the destroyed Agar Town, one that vividly recalls it to my mind as I recollect it as a boy and young man. He writes "those who knew the district at that time have no regret at the change. Time was when the wealthy owner of a large estate had lived here in his mansion; but after his departure the place became a very 'abomination of desolation.' In its centre was what was termed La Belle Isle, a dreary and unsavoury locality, abandoned to mountains of refuse from the metropolitan dust-bins, strewn with decaying vegetables and foul smelling fragments of what had once been fish; or occupied by knackers' yards and manure making, bone boiling, and soap manufacturing works, and smoke-belching potteries and brick-kilns. At the broken doors of mutilated houses canaries still sang, and dogs lay basking in the sun, as if to remind one of the vast colonies of bird-fanciers and dog-fanciers who made Agar Town their abode; and from these dwellings came out wretched creatures in rags and dirt, and searched amidst the far-extending refuse for the filthy treasure, by the aid of which they eked out a miserable livelihood; whilst over the whole neighbourhood the gas works poured forth their mephitic vapours, and the canal gave forth its rheumatic dampness—extracting some of the more poisonous ingredients in the atmosphere and spreading them upon the surface of the water in a thick scum of various and ominous hues. Such then was Agar Town before the Midland Railway came into the midst of it."

It will be seen from this that whilst the L. and S. Western terminus at Waterloo, in recent days, has wiped out an entire parish, the Midland Company, in the creation of St. Pancras Station and its approaches, in the sixties, practically demolished a whole town.—Yours obediently, HARRY HEMS.

The Emperor's new Portrait.—Professor Herkomer's portrait of the German Emperor on which he is now engaged at Berlin is to be in enamel, and will be the largest portrait ever executed in this medium.

The Catacombs at Rome.—Subscriptions are invited for the further exploration of these catacombs. Those interested are requested to apply for further information to Mgr. P. Crostarosa, Via del Quirinale, 24, Rome, secretary of the Commissione di Archeologia Sacra.

Surveying and Sanitary Notes.

Street Improvements at Chesterfield.—At a meeting of ratepayers of Chesterfield held on March 19th (convened by the Mayor), a resolution was adopted expressing approval of the three following schemes:—(1) Widening of Burlington Street and Knivesmith Gate by setting back the properties lying between the north side of Dr. Green's premises in Burlington Street and the north-west corner of the Churchyard, in Holywell Street; (2) a new street from Packer's Row in a north-easterly direction into Burlington Street; (3) a new street being a continuation of Gluman Gate, to the south side of Newbold Road at its junction with Sheffield Road.

The Sanitary Institute.—The ordinary general meeting of the Sanitary Institute was held last week at Parkes' Museum, Margaret Street, W., Sir Thomas Salt, vice-president, in the chair. The annual report stated that the question of additional premises for enlarging the museum and extending the work of the institute had received the careful consideration of the council, and it had been decided to start a building fund. There had been a steady increase in the number of students brought to the museum by lecturers and demonstrators, showing an appreciation of the teaching value of the museum.

Refuse Disposal was dealt with by Mr. James Munce, A.M.I.C.E., M.S.I., before the Belfast Society for the Extension of University Teaching on Wednesday last. The cost of carting refuse, he said, was a very heavy item, and those responsible for the work were turning to motor vans. Recent reports proved that the work could be done by these for about 3s. 4d. per ton per mile, exclusive of repairs and depreciation. They carried from 3½ tons to 6½ tons at a speed of between five and six miles an hour. Sir W. H. Preece, C.B., in his presidential address to the Sanitary Institute last year, stated that the best code of sanitary law in the world was that given by Moses to the Israelites, as recorded in the Book of Leviticus, and the fact that the Jews were the most healthy people in the world was largely due to their burning of refuse outside the walls of their cities. Paris, Mr. Munce said, had found that cremating refuse was preferable to raising ramparts with it as in years past; and their medical friends regarded that method as most effectually disposing of disease germs.

Engineering Notes.

For Electric Lighting Extensions at Rathmines the Council propose to spend £21,000. A Local Government Board enquiry was held last week.

For Water Supply and Sewage Disposal Works at Burnham £2,500 are proposed to be spent. A Local Government Board enquiry was held recently into the application.

The Institution of Civil Engineers held its annual dinner at the Merchant Taylors' Hall on March 21st. Sir William Preece, past-president, occupied the chair in the absence of the president, Sir Douglas Fox, and about 250 sat down to table. "The Institution" was proposed by Lord Balfour of Burleigh, who metaphorically characterised the profession of the civil engineer as the one which laid down the rails upon which our civilisation ran. No profession had made greater progress in the Victorian Era. A century ago a Dutchman had to be employed to supply London with water, and a Swiss to build a bridge at Westminster, but now we were able to supply other nations with skilled engineers. In modern life we did not so much require men of much knowledge as men who knew how to apply their knowledge in emergency; therefore he expressed his unbounded astonishment that the Institution should have succumbed to the age for examination.

L.C.C. Electric Tramways.—A Bill promoted by the London County Council to enable them to use electricity as the motive power on their system of tramways came before a Select Committee of the House of Commons last week. Mr. Pope, Q.C., said that the conduit system, which avoided many difficulties, would promote uniform and continuous connection and would give the least possible disturbance of electrical equilibrium, by the use of insulated return, would be generally applied. Mr. J. Williams Benn, chairman of the Highways Committee of the London County Council, stated that they had effected reductions of fares, and would be able to effect further reductions by electric traction, which was about 3d. per mile cheaper than horse traction. This would yield a profit of £81,000 per annum above that yielded by horse traction. The streets of London would be relieved of 15,000 horses, less space would be occupied, and a higher speed would be attained. Dr. Kennedy gave evidence in favour of the conduit system. It would be tried between Tooting and Westminster on part of the line, the other part being worked on the surface contact system. The Committee passed the preamble of the Bill.

Keystones.

A new Primitive Methodist Chapel at Penzance has been erected at a cost of £1,500. The front is of cut granite, the main feature being a central window filled with cathedral glass.

Hull Royal Infirmary Extensions.—It is proposed to add an east wing to this building at a cost of £20,000, and it is stated that operations will be commenced before the summer is out.

New Church at Aberdeen.—A new church is to be built for the congregation of Free Ruthrieston, Aberdeen, in front of the existing church buildings in Broomhill Road. The church will provide sitting accommodation for 550 worshippers and will cost £3,600. The work is to be proceeded with at once. Messrs. Brown and Watt, of Aberdeen, are the architects.

Old Cockington Church is undergoing considerable repair. The whole of the plaster of the western part of the nave has had to be removed and it has been found necessary to strengthen and brace together the timbers of the roof; these have been in position some hundreds of years, but the heart of the oak is so hard that ordinary tools cannot be used. A blacksmith's drill has to be brought to bear upon it.

Peterborough Cathedral, which at present is being restored, was originally the monastery of Medeshamstede (the homestead in the meadows), and was founded by Peada, King of the Mercians, in the seventh century. In the ninth century it was utterly destroyed by the Danes. It was rebuilt, and though some parts of it may be seen to this day, it was plundered and destroyed by Hereward, the Saxon patriot, in 1116. Next year John of Sais commenced the building of a new monastery, and the church then begun is the minster we now see.

Archæological Discoveries in Paisley Abbey.—The work of excavation in connection with the restoration of Paisley Abbey is being carried on daily, and several interesting discoveries of archæological interest have been made during these operations. Among these are two finely-chiselled stones, 5ft. 8in. by 1ft. 10in., which were found at the bottom of the foundation of the west pier of the tower, lying side by side in a bed of sand. On the face of each are elaborately carved crosses, which are so well preserved that they might be passed off as recent work, though they must be at least 600 years old. Built into the walls are carved jamb mouldings, fragments of finely-moulded bases and capitals, and these, if not also the above-mentioned stones, it is thought, must have been part of the ancient monastery on the site of which the Abbey now stands.

The late Mr. W. H. Tonks, of Birmingham, died worth £90,374.

Theatre Francais.—A credit of 2,200,000 francs (£88,000) has been voted for the rebuilding of this theatre.

A new Board School at Pebbles is to be built at a cost of £12,000. A site has been secured at the north-west end of the town.

Notice of Removal.—Mr. G. H. Bruton, F.R.I.B.A., architect, surveyor and valuer, has removed his offices from 15, Queen Street, Cardiff, to Alexandra Buildings, 119, Queen Street, Cardiff.

The Work of Completing South Kensington Museum has at last been commenced. To prepare the foundations will probably take about two years, and some five or six more are likely to elapse before the superstructure is completed.

The Sussex Archæological Society held its annual general meeting at the Town Hall, Lewes, on March 21st. As a difficulty had arisen about the turning-up of the ground by the proposed excavations at Pevensey Castle, it was decided to spend the money allocated for excavations at Lewes. It was stated that a full paper was being prepared on the mural paintings in Sussex churches, and would be printed in the new number of the Society's journal. Mr. P. M. Johnston read a paper on "Ford and its Church," and Mr. Boyson one on "The Black Marble Columns at Lewes Priory."

New Stock Exchange Buildings in New York.—So great has been the increase of business on the New York Stock Exchange since the war with Spain that the present building has been found inadequate, and a new building, which will cost £600,000, is, therefore, about to be built, but in order that business may not be interrupted the new structure is to be put up in sections. Instead of the present low house, the new one will be ten storeys high on the Broad Street side and may run up seventeen storeys on the opposite or New Street side, where the frontage is about 152ft., as against 135ft. on Broad Street.

Oriental Architectural Works.—The following illustrated books on Oriental architecture (published by Messrs. Kegan Paul, Trench, Trübner and Co., Ltd., Paternoster House, Charing Cross Road, W.C.) will be useful to some of our readers:—"Mogul Architecture of Fathpur-Sikri," by Smith (4 vols., £5); "Mohamedan Architecture in Gujrat," by Burgess (£1); "Portfolio of Indian Architectural Drawings," by Smith (Vol. I, 12s.); "Technical Art Series of Illustrations of Indian Architectural Decorative Work," published yearly since 1886, price from 2s. 6d. to 6s. each part.

Royal Parks and Pleasure Gardens.—The following extra items of expenditure on works to be executed in the coming financial year have been sanctioned by the Treasury:—Rebuilding stables at Bushey Park, £350; general improvements and completion of new footpath in Greenwich Park, £750; reconstruction of plant-houses, &c., in new Frame Ground, Hampton Court, £1,000; improvements near the Trophy Gate, Hampton Court, £250; purchases for the museums, Kew Gardens, £200; completion of new filter beds, ditto, £185; new potting shed, ditto, £100; experimental well, ditto, and laying new main and continuing works, £900.

New Hydro for Whitby.—A new hydro-pathic establishment, costing from £30,000 to £35,000 and to be called Cliff Hydro, is about to be erected at Whitby. The site is nearly opposite the Metropole Hotel, and the plans, which have been prepared by Mr. Harold G. Walker, architect, of Whitby, show a brick and stone building in the French Renaissance style. It is to contain smoke room, billiard room, dining room about 50ft. square, drawing room about 60ft. by 30ft., reading room, a very large recreation hall and lounge, and a big lounge at the entrance. There will be 170 bedrooms and baths of all kinds conveniently distributed, besides which a suite of Turkish baths is to be provided in the basement. The new hydro is to be opened by Easter 1901. The surveyor for the work is Mr. W. Hoffman Wood, of Leeds.

A new Physical Laboratory at Kew is to be built at a cost of about £12,000.

A new Rectory House for Radcliffe Church has been built at a cost of about £2,000.

Change of Address.—Mr. P. Morley Horder has removed his offices from 118, New Bond Street, to 148, New Bond Street, W.

Large Timber Fire.—Messrs. J. Lemanton and Sons' timber yard at Millwall, E., was gutted by fire on Saturday. The damage is estimated at £40,000.

An Arts and Crafts Exhibition at Huddersfield has been opened at the Municipal Art Gallery, and will remain open until Easter.

Housing Question at Merthyr.—The Merthyr Urban District Council has decided to build 500 cottages for the working classes in the district.

A new Free Church at Culter, Aberdeen, is to be built from designs by Messrs. D. and J. R. McMillan, selected in competition. The cost is £4,000.

A new Fever Hospital at Grimsby has been erected by the Corporation. It is about a mile from the town, at Little Coates, and is of corrugated iron.

Christ Church, Rathgar, is being enlarged under the supervision of Mr. W. M. Mitchell, architect, Belfast. Mr. W. Creighton, of Rathgar, is the builder.

The Statue of Alphonse Daudet, upon which M. Falguière, the sculptor, is at work, is not yet finished; but it will be sent to Nîmes early next month and deposited in the Square de la Couronne.

A DISPUTE ABOUT DRAINS.

THE recent case in the Court of Appeal of the *Vestry of the Parish of St. Mary, Islington v. The Hornsey Urban District Council* was an appeal against a decision of Mr. Justice Kekewich's. The object of the action was, in substance, to compel the defendants to disconnect some sewers in their district from a sewer belonging to the plaintiffs in the Stroud Green Road, North London, and to restrain the defendants from permitting any future connection of drains or sewers in their district with the said Stroud Green Road sewer. In 1865 the Tottenham and Hampstead Junction Railway Company constructed the above-mentioned sewer under part of their railway and along the Stroud Green Road, and this sewer was connected with, and discharged into, the metropolitan sewer known as the northern high-level sewer, vested in the London County Council. The Stroud Green Road formed part of the boundary between the parish of St. Mary, Islington, and the parish or district of Hornsey. In 1868 the owners of a piece of land in the Hornsey district proceeded to develop it as a building estate, sewers being made under each of the roads formed and connected with the plaintiff's Stroud Green Road sewer. The plaintiffs alleged that the result of this was that after heavy rains the discharge of the additional sewage and surface water from the sewers in these roads choked up the Stroud Green Road sewer and rendered it incapable of carrying off the sewage and surface water from the part of the parish of St. Mary, Islington, which, as the plaintiffs alleged, it was constructed to drain; so that serious floodings had been caused, endangering the health and property of the inhabitants and ratepayers of that parish. The defendants denied that the sewer in question was constructed for the sole benefit of the parish of St. Mary, Islington, and asserted that it was constructed partly at the expense of the owners of property in the defendants' district abutting on the Stroud Green Road, and for the benefit of the owners and occupiers thereof; that the defendants had acquired a right by prescription to drain into the sewer; and that, although the sewers in the above-mentioned roads were vested in the defendants, under the Public Health Act, 1875, that vesting gave them no right to stop up the connections with the Stroud Green

Road sewer. Mr. Justice Kekewich dismissed the action, declining to grant an injunction.

The appeal was heard on February 22nd, 23rd, 26th, and 27th, and on March 20th the Master of the Rolls delivered the considered judgment of the Court allowing the appeal. He said: The appeal in this case raises two important questions—namely, whether the defendants are entitled to have the sewage from part of the parish of Hornsey pass down a sewer called Stroud Green Road sewer, some part of which, at all events, is in the parish of Islington and is vested in the plaintiffs; and secondly, whether, if this question is decided against the defendants, the plaintiffs are entitled to an injunction to prevent such passage, seeing that, if it were prevented, a very serious public nuisance would be the consequence. The learned judge has dismissed the plaintiff's action and they are the appellants. The order of the Court was as follows: Allow the appeal and reverse the judgment of the Court below, and order the defendants to pay the costs of the action and of the appeal. Declare that the Stroud Green sewer in the pleadings mentioned is throughout its whole length in the parish of Islington, and is vested in the plaintiffs, and that the defendants are not entitled to send sewage from any sewer in the parish of Hornsey into that sewer without the consent of the plaintiffs. And let the plaintiffs be at liberty to apply to the judge to whose Court this action is attached at the end of twelve months from the date of this order for an injunction to enforce their rights as above declared.

Masters and Men.

The Lanarkshire Joiners have struck against the proposed reduction in wages from 9d. to 8½d. per hour.

The Bradford Plumbers' Strike has been settled. The masters have given the 9d. per hour demanded, whilst the men have made certain concessions in regard to by-laws.

The Aberdeen Joiners' Strike.—The Aberdeen Master Builders' Federation have resolved to recommend to the several associations of master builders forming the local Federation that each of these associations shall arrange for all its members to pay off the whole of their men in order to settle the dispute. This lock-out would affect not only the joiners, but masons, slaters, plumbers, plasterers, painters, &c., to the number of about 2,000.

London Plasterers' Dispute.—The dispute between the masters and employees in the plastering trade which has been going on for the past three weeks has been settled, and the men have returned to work. The Conciliation Clause, which has been the main subject of dispute, has been altered, deleting the part referring to the awarding of damages against either party in default, and substituting an undertaking on the part of both masters' and men's associations either to inflict a fine upon, or to expel the members or member who may transgress the rules. The masters have also officially recognised the advance of 1d. per hour demanded by the men, and a clause referring to the payment of fares has also been inserted in the rules.

Cardiff Corporation Contracts.—A deputation of Cardiff Master Builders waited upon the Cardiff Public Works Committee at their meeting last Thursday with reference to three clauses for insertion in the corporation form of tender, which the master builders considered essential to protect themselves. The first is a strike clause and the second a lock-out clause. The form of contract the corporation is asked to adopt is the one adopted by the Royal Institute of British Architects. The third point is that of arbitration as to whether the architect's decision, upon points arising between himself and the builder as to the conduct and condition of the work, should be final. The chairman of the committee asked the deputation to submit the points they wished to bring

before the committee in writing, when the matter would be gone into.

The Chicago Building Dispute.—The great strike in the building trades in Chicago has entered upon a rather strange phase. The object of the working-men is to secure the employment of unionists only. Building contractors, in opposing this demand, obtained the assistance of dealers in plumbers' supplies, who agreed not to sell to any plumber who did not renounce his union. The plumbers responded by ordering all members not to handle materials sold by Chicago dealers, and the boycott has been so effective that sales have fallen to an unprecedented point, and business is conducted at a loss which, if continued, means the ruin of half the firms engaged in the struggle. To avoid disaster, they are removing all distinctive marks from their materials, and the work of union plumbers in identifying it will thus be rendered doubly difficult and expensive. Whatever answering device the union adopts, it would appear that the boycott policy on both sides has failed.

New Patents.

These patents are open to opposition until April 28th.

1899.—Fanlight Openers.—4,199. R. F. BLACKETT, Newcastle-on-Tyne. A segmental split arm is pivoted to the frame and passes through a fastener fixed on the light itself. This fastener has a spring bolt for locking the arm in position, and a pulley through which a cord passes for operating the window.

Tough Incandescent Mantles.—4,589. O. HENTZE and H. MÜLLER, both of Leipzig, Saxony. To make the mantle proof against rough usage it is impregnated with Carlsbad salts and Carlsbad mineral spring-water. This, it is claimed, increases rather than decreases the candle-power.

Fixing Back-plates of Locks.—6,113. C. R. HECKFORD, Wolverhampton. Instead of using screws to secure the back-plate, this is sprung into position by pressing out the fore-end of the lock case until the back-plate passes under a shoulder.

Colour Spraying Apparatus.—6,608. G. E. HOLLOWAY, London, E.C. A closed vessel of tin or copper floats on, or is suspended in, the liquid to be applied, and receives an internal supply of compressed gas or air. On its upper surface are nozzles with spreaders, fed by tubes that pass through the vessel into the liquid.

Dovetailing Machines.—8,272. J. PARNALL, J. BARTER, and W. PANES; all of Bristol. The machine has movable bearings and cutters, enabling the positions, sizes, and number of the dovetails to be varied as required, and a table for doing mortise and pin-dovetailing upon which may be detached and a cramp substituted, so that the machine will then dovetail drawer-fronts.

Sectional Hot-Water Boilers.—8,368. J. KEITH, London, E.C. Combined with a main hot-water boiler composed of water-containing sections jointed together and enclosing a central combustion chamber is an auxiliary water-jacketed furnace, having a central fuel space with a firing door at the top and a fire-grate at the bottom, the fuel space of the heater being connected with the combustion chamber of the main boiler by a flue.

Draught Excluders.—8,416. J. SWARBRICK, Salford. At the bottom of the door several brackets with rollers at their lower ends are pivoted, and to them is attached a strip of cloth for excluding the draught.

1900.—Wall Ties.—1,220. O. IMRAY, London, E.C. (J. G. McDowell, Pittsburg, U.S.A.). The tie consists of a strip of metal (preferably steel) with a right-angled lug at one end, the other end (that is, the outer end) being jagged at the edges, with the teeth inclining inwards.

The following specifications were published on Saturday last, and are open to opposition until

May 7th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1898.—24,982, SMITH, appliances for overhead electric traction.

1899.—1,808, RAMSAY, hangers for sliding doors and shutters. 4,138, MUGNA, apparatus for washing or purifying smoke from furnaces or fireplaces. 4,275, GIBBS AND DOWNING, sustaining apparatus for pulley blocks and lifting tackle. 4,336, BRANDSTAEDTER, bolting machines. 4,389, ADAMS, means for operating fanlights. 4,907, THIRIAULT, treatment of sewage. 6,194, GATESHEAD STAINED GLASS CO., LTD., and SNEE, combined process for working designs in or upon plate, sheet, or other flat glass. 6,648, MORGAN, stoneware drain pipes. 6,766, J. DUCKETT AND SON, LTD., DUCKETT, AND DUCKETT, channel gulleys, sinks, and sink fittings. 6,858, MERRILL, automatic flushing syphon. 7,182, PAIDASSY, hydraulic apparatus for closing doors. 7,616, WORCESTER ROYAL PORCELAIN CO., LTD., and RANFORD, decoration of articles of porcelain and other earthenware, glass, &c. 7,864, STANLEY, surveying instruments. 8,030, MARCHAND, centrifugal pumps. 8,058, HELMECKE, process for manufacturing durable incandescent gas mantles. 8,323, BOURGEOIS, paint containers. 8,654, PILKINGTON and ORMANDY, treatment of waste sand from glass grinding or polishing, or certain other sand or minerals containing iron. 8,722, JOHNSON, construction of plastic and stiff-plastic brick machines. 8,760, CHISHOLM, KIRK AND CHISHOLM, wrenches. 8,883, WATSON, safety guard for slate-cutting machinery. 9,047, HOLDEN, apparatus for closing gates. 9,055, HEINZEL, chimney for incandescent gas lamp burners. 9,380, FIRTH, BENTHAM and STOTT, incandescent gas burners. 9,784, LANTZKE AND JUENGER, non-conducting and fireproofing materials. 11,041, ERNEST and PHILLIPS, manufacture of material for purifying acetylene gas. 14,169, CANDLISH AND GODDARD, portable elevator for use of builders for bricks, slate, mortar, &c. 14,336, GUEST, spanners, pipe wrenches, and similar tools having adjustable jaws. 20,074, SABINE and SABINE, edge pan runners for grinding clay. 20,263, WAREHAM, window blind fittings. 24,699, ALLEN, method of making metallic castings.

1900.—703, BLÉRIOT, acetylene generators. 953, BODE, folding gates. 1,142, McKIBBEN, devices for bending pipes, tubes, bars, &c. 1,167, FABRE, adjustable suspension device for electric lamps. 1,273, GRIMWADE, method of decorating china and earthenware. 1,385, HOFFMAN, sectional boilers for hot-water heating purposes. 1,492, DYMOND (Clarke), heat radiators. 1,554, LEYSEN, straight arches. 2,220, MCGREGOR, apparatus for excavating or dredging earth.

New Companies.

British and Italian Mosaic Co., Ltd.

This company has been registered in Scotland with a capital of £1,500 in £1 shares, to acquire the business of G. Zani, Ricci and Co., Glasgow, and to carry on that of marble and glass mosaic manufacturers, &c.

Fenarth Cottage Improvement Co., Ltd.

This company was registered on March 3rd, with a capital of £2,000 in £10 shares to acquire any real or personal property, and to develop, deal with, work, and turn to account the same; as builders and contractors.

Metropolitan Brick Company and Builders' Supply Association, Limited.

This company was registered on March 14th, with a capital of £10,000 in £1 shares to acquire certain premises in White Hart Lane, Tottenham, and to carry on the business of brick and tile manufacturers, potters, carpenters, engineers, &c. The first directors (to number not less than two nor more than seven) are H. Kerby and C. H. Hunter. Registered office: 4, Lancaster Place, W.C.

John Cooper and Son (Nottingham), Ltd.

This company was registered on March 8th with a capital of £3,000 in £1 shares to carry on the business of builders, contractors, stone merchants, brick and tile makers, &c. Registered office: 11A, Ayr Street, Nottingham.

The Avon Bridge Granite and Whinstone Quarries, Limited.

This company has been registered in Scotland with a capital of £12,000 in £1 shares to acquire and carry on Craigbank Quarries, at Avonbridge, belonging to Allan Waugh, of Craigbank.

The Notkin Syndicate, Limited.

This company has been registered in Scotland with a capital of £10,000 in £1 shares to acquire letters patent of an invention for automatically and continuously carburetting air for illuminating and heating purposes. Registered offices: 28, Queen Street, Edinburgh.

John Morgan and Co., Limited.

This company was registered on March 12th with a capital of £1,608 in £1 shares to acquire the business carried on by the executors of the late John Morgan at 23 and 25 Holly Street and 52, Richmond Row, Liverpool, and to carry on the business of wholesale and retail paint, oil, colour and varnish merchants, &c.

Thomas Woodward and Son, Limited.

This company was registered on March 14th, with a capital of £3,000 in £1 shares to carry on the business of carmen and contractors.

Cope, Roberts and Co., Limited.

This company was registered on March 8th with a capital of £8,000 in £1 shares to carry on the business of dry-salters, ship store dealers, oil merchants, and manufacturers of and dealers in petroleum products, colours, varnishes, soaps, glue, turpentine, enamel, blacking, &c. The first directors (to number not less than three nor more than four) are G. Cope, T. S. Roberts, G. Kyffin-Taylor and Joseph H. Glover.

Hartlepool Cement Company, Limited.

This company was registered on March 17th with a capital of £14,000 in £5 shares to acquire land at Longhill, Seaton Carew, West Hartlepool, Durham, together with the cement works, plant, and machinery, &c., belonging to G. POTTERY WORKS, MIDWAY,**

Near Burton-on-Trent

APRIL 4, 1900.
NO. CCLXIX.

EFFINGHAM HOUSE,
ARUNDEL STREET,
STRAND, W.C.

here. No. 68, by C. J. Watson, "York Minster." Nos. 69, 70, Ponte Vecchio, Florence, and Santa Maria Salute, Venice, by Arthur Evershed. No. 76, Cloisters, Christchurch, Oxford, an example of aquatint, by Charles O. Murray. No. 82, a beautiful little Dutch belfry, by Miss C. M. Pott. No. 85, the Cloisters, Chester Cathedral, by L. Dectur. Nos. 87 and 119, the old "Spaniards' Inn," Hampstead, and Earl's Eye, in the county of Chester, a wonderful panorama of flat-land laid out on geometrical lines. These two by W. Monk. No. 90, Old

"Unlovely London." A SHORT time ago Mr. Richard Whiteing opened a debate at the Passmore Edwards Settlement on the unloveliness of London, and a good deal of correspondence has emanated from the remarks which were made during the course of the lecture. It does not seem a matter of vital concern whether the author of "No. 5, John Street" considers London the ugliest city in Europe, with the possible exception of Madrid, or merely the ugliest capital; it is at least apparent that, in the lecturer's opinion,

An Architectural Causerie.

Architectural Etchings. AN architect, not merely an engineer, is expected to have a sympathetic understanding of other arts than his own, and etching is certainly one of the things he should know something about, for what meets the eye in a building, either to please or offend, is the outline, and, although not his only possession, the etcher's command of line is what distinguishes his work from another's. Let Rembrandt's most exquisitely etched little indications of landscape be compared with his drawings in pen and wash; it will immediately be seen how happy in the hand of the master is the precise little etching-needle and how the natural value of line is emphasised and increased by the action of acid. The etched line is a bitten line, and such is its strength that it must either give pleasure or pain—the latter if rightly placed. A superfluous line is a terrible eyesore here. There is excellence and its reward in mere reticence. What has been described as "classical parsimony" in the writings of one of our masters is the *sine qua non* of the etcher, and of a great many artists besides.

There is a broad distinction between etching proper and dry-point, which is in effect a peculiar kind of engraving, or freehand sketching on copper—a thing by no means easy, and one which only a few should attempt. The rich and velvety effects of burr are peculiar to this kind of etching, if etching it must be called, for the plate is not cleaned and the impression is as much from the ridge as the furrow. Considering the frailty of such a surface, it follows that a plate which has been dry-pointed will yield but a few impressions. The perfection of this kind of work may be seen in the exhibition now open of the Royal Society of Painter-Etchers and Engravers in the daring examples exhibited by M. Helleu. The bewitching creature called Alice, who leans on her elbows and looks, is something to see and to dream of, whether one thinks of the manner of work, or, what is more likely, of the enchantress, with her eyes so quietly fastened upon you that you are chained, so to say, to the spot. Her raiment may have been of velvet or not, but such is the effect of the burr that it would be supposed to be.

The reader of this short paper may feel that I am only wasting his time, since I half-promised to tell him what etchings of buildings there are, but there is this very obvious advantage in being guided by some sort of principle that it reduces the number of things to be praised, whether they represent churches or chamber-maids, by one-half at the very least, and even so there remains enough of really desirable etchings to provide one with talk for an hour. The most delightful of Mr. Axel Haig's elaborate architectural plates is his representation of The Baptistery, San Marco, Venice, No. 20. No. 52, one of three bits of "Vanished Hampstead," by A. W. Bayes, a snow scene, including a Georgian house front, seems to reflect to perfection the mood of the artist, and, notwithstanding its diminutive size, is impressive as anything

ST. MARY'S CHURCH, BRIGHTON.

WILLIAM EMERSON, ARCHITECT.

Archway, Bedford, by M. Bramley-Moore. All these are things to be noticed, and last, most important of all from this limited point of view, are three views of New Inn, Strand—about to be demolished—No. 234, by Walter W. Burgess, which are in themselves as telling as they are beautiful, and awaken feelings of embittered regret, which must, I suppose, be repressed. It is a pity that these and some others cannot be reproduced, but the object of writing is, after all, to persuade people to see the real things, and the quality of an etching, like the bouquet of a wine, may be said to be incommunicable.

ERNEST RADFORD.

it is a city composed mainly of narrow, dull thoroughfares, whose tortuous, haphazard streets are ill-planned, ill-conceived, ill-kept—hence "Unlovely London." One might be tempted to question the wisdom of debating such a subtlety as "unloveliness," so impossible is it to define, so much is it a matter of sense, feeling and intuition; is there, one wonders, any arbitrary standard—any rightness or wrongness in loveliness? As illustrating the difficulty of arriving at any consensus of opinion upon such a subject, no more apposite instance could be found than the divergency of ideas produced in the debate on Mr. Whiteing's lecture.
